

## Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

## Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

## Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

Auto-intoxication, Dr. Kovacs, 828  
Avenues for medical practice, Dr. Kyles, 486

## B

Bacilli treatment of foot and mouth disease, 406  
Bacilli in sputum, 662  
Bacilli of dysentery, 38  
Bacillus of syphilis, discovery of the, 23  
Bacillus tuberculosis, direct infection with the, Mr. S. Boyd, 27  
Bacterial action of serum, 239  
Bacteriology, special instruction in, 215  
Baizer, Prof., tinea tonsurans, 877  
Banti's disease, 578  
Bardwell, Dr., pulmonary tuberculosis, 553  
Barlow, Dr., individualism in medicine, 381  
Barker anatomical prize, 452  
Bathing fatalities, 46  
Beard, Mr., sterilisation of flexible catheters by boiling, 380  
Beauty making, 19  
Beer poisoning sensation, 178  
Beifast, 323  
Berl-berl at Liverpool, 792  
Birmingham consultative institution, 392, 554  
Birmingham libel case, 178  
Births—end of each No.  
Birthday honours 528

Bishop, Mr., demonstration of changes occurring in uteri in which fibro-myomata are present, 677  
Blake-Knox, Dr., aetiology and prophylaxis of enteric fever in South Africa, 207  
Blennorrhoea neonatorum, 140  
Blood pressure in fevers, 65  
Blue electric light, 339  
Bogus doctor, a, 400, 453  
Bore callus, 546  
Bone-setters, 525  
Bone-setters and quacks, 818  
Boric acid, 391  
Botanist censured, a, 25  
Boyd, Mr. S., direct infection with the bacillus tuberculosis, 27  
Bristol university college, 533  
British laryngological association, 505  
British medical association, 123; annual meeting, 151  
British medical association meeting, 1902, 248  
British pharmaceutical conference, 50  
Broken ribs overlooked in hospital, 222  
Bronchitis in children, Dr. Marfan, 351  
Brouardel, Prof., prevention of consumption, 107  
Brown, Mr., the Harvard lectures, 536, 561, 595  
Buck, Mr., treatment of tuberculosis by urea, 163  
Burroughs, Wellcome and Co., fate of, 102  
Butter commission, a, 50  
Buxton spa, 46  
Byers, Dr., nineteenth century progress in obstetrics and gynaecology, 131

## C

Cabman and street accidents, 19  
Cochin congress, 64  
Caecodylic medication, 114  
Caesarian section, 42, 661  
Caesarian section, Dr. Kerr, 484  
Calcium carbide, 74  
Campbell, Dr., treatment of metritis, 325  
Camphor in the treatment of varicose ulcers, 73  
Can anaesthesia be induced during sleep? 73  
Cancer, 419  
Cancer clinic, proposed, 812  
Cancer of the stomach, Dr. Robin, 88, 188  
Cancer, the study of, Mr. Meldon, 510  
Cape medical council, 424  
Capital punishment, 516  
Capo, Dr., x-rays in the diagnosis of tuberculosis, 161  
Carbolic acid as a dressing for burns, 392  
Carbolic acid in septic wounds, 358  
Carbuncle, 690  
Carcinoma, 294  
Carcinoma question, 445  
Cardiac drugs and the vaso-motor treatment, Dr. Gottlieb, 85  
Cardiac failure, acute, 22  
Cardiac musculature, disease of the, 240  
Cardiac tuberculosis, 14  
Careless death certification, 424  
Cash value of a finger, 67  
Casumen, 588

Castel, Dr., epithelioma and syphilis of the face, 623  
Casting out the mote, 442  
Cavendish lectures, the, Sir R. D. Powell, 1  
Cedron seeds, 342  
Centenarians, 688  
Cerebral syphilis, 439  
Certification of lunatics, 250  
Change of hospital name, 675  
Changes in the staff at St. Bartholomew's hospital, 613  
Charing Cross medical school, 25  
Charwoman abortionist, a, 617  
Chemist-apothecary fined, 99  
Chemists and druggists' exhibition, 253  
Chigoe, the, 222  
Children and the new beer regulations, 688  
Chinese laundresses, 367  
Chinosol, 334  
Chiver's Cambridge lemonade, 101  
Choice of direct representatives, the, 169  
Cholelithotomy, 307  
Chorea and arsenic, 241  
Chorea and rheumatism, 44  
Christeanu, Dr., the vomiting of pregnancy, 803  
Christian science "testimony" meetings, 248  
Chronic endometritis, 115  
"Chronic harmless lunatics," 170  
Chronic pelvic exudation, 416  
Cigarette smoking, 176  
Cinnamon and tuberculosis, 140  
Coates, Dr., investigation into the presence of infective material in dwellings occupied by consumptive persons, 134  
Cocaine in obstetric practice, 681  
Cocaine poisoning, 122  
Coincidence of the spinal cord, 69  
Cold tub, the, 696  
Coleman, Dr., medical experiences in South Africa, 300  
Coler, surgeon-gen. von, death of, 240  
College of preceptors, 129  
College of safe medicine, the, 195  
College representation on the G. M. C., 611  
Colmeris, don M., 25  
Comba log of tuberculosis, Dr. Koch, 105, 118  
Comparative medicine, 523  
Compensation for condemned meat, 126  
Complimentary dinner to Surgeon-General Jameson, C.B., 121  
Concentration camp mortality, 641, 670  
Congress of tuberculosis, 45, 97  
Connector of nasal disease with cataract, the, 197  
Constipation, 415  
Constipation, Dr. Oldfield, 854  
Consumption hospitals, 89  
Consumption of salt, the, 368  
Contagiousness of alopecia areata, 97  
Contagiousness of psoriasis, 552  
Continental climatic stations, 88, 306  
Contract medical attendance, 479  
Contusion of intestines, 415  
Cooler, Mr., inoperable cancer, 435  
Copeman, Dr., modern methods of vaccination, 654

## CORRESPONDENCE.

"A lethal coin," 451  
Anderson fund, the, 49, 128, 678  
Attitude of pharmacists to patent medicines, 74

Banti's disease, 615  
Biological test, 297, 321, 345, 370, 396, 449, 478  
Cancer, 450  
Cheltenham meeting, the 99  
Chloroform death, 75  
Congress on tuberculosis, 202, 396, 426  
Counter-prescribing, 478  
Covering a bone-setter, 585  
Cure of consumption, 502  
Damages for premature burial, 585  
Deaths under chloroform, 558  
Degrees for London students, 530, 557  
Diet in relation to the cause and cure of constipation, 450  
Difficulty of diagnosis in infectious diseases, 200  
Election of direct representatives, 370, 503  
"Evasive" secret of cancer causation, the, 580, 558

## The Cabendish Lecture

ON

### ACUTE CARDIAC FAILURE. (a)

By Sir RICHARD DOUGLAS POWELL, Bart.,  
K.C.V.O., M.D.

"ACUTE heart failure" is, I admit, a misleading phrase, suggesting, perhaps, some separate disease of the organ, but of course it only implies the culmination in temporary or permanent arrest of the cardiac function of a variety of conditions damaging to texture and exhaustive to nerve power or muscular energy.

We cannot perceive aright the heart and its mechanism, nor appreciate duly its modes of failure, unless we bear steadily in mind the fact that it is but a part, differentiated for special reasons, of a complete cardio-vascular tubal system containing the blood. The tubes are not passive tubes sluiced by a central force pump; on the arterial side the powerful rhythmic pulsations of the heart are so modified and restrained by the elastic and muscular action of the vessels as to ensure a safe and adequate stream of blood throughout the body. Whilst on the venous side the position of valves, the action of adjacent and often ensheathing muscles, the impetus of lymph and chyloferous tributary currents, and the constant but rhythmically increased thoracic aspiration, help to maintain the blood movement.

I need only hint at the large influence of the nervous system which has in course of evolution become so specialised with regard to the heart and vessels. The cerebro-spinal nerves, the sympathetic system and a department of the nervous system—the vaso-motor nerves—in touch with the preceding and yet under guidance from a separate centre, all take part in controlling the heart's doings and in regulating the blood supply to each organ, according to its functional requirements, which vary from time to time. Finally, there is held in the tightening and relaxing grasp of this complex tubal apparatus, the blood itself, a living tissue, whose constant variations, both chemical and physical, in health and disease, affect the facility of the capillary flow and influence the tonicity and nutrition of the circulatory apparatus. Can we look into this complex mechanism, which I have so barely sketched, in which physical, chemical, and vital agencies are so intimately mingled, without a feeling of wonder that it should hold good unceasingly to the allotted term of life, and that so few lives should be brought to a premature close through heart failure? A chapter on compensatory adaptations has yet to be added to our text books on medicine for our better understanding of many such problems.

With such an infinite number of contributory

factors, acute cardiac failure cannot be a simple question, and if I, bound by the stern limits of time and the more compelling limitations of my ability, approach it from the more concrete, clinical, and practical side, it is from no want of appreciation of the manifold intricacies of the subject, and it is with a very humble sense of our indebtedness as practical men to those who by patient labour in the laboratory have given us so large an insight to help us to solve the problems that come before us in our daily work.

A most obvious cause of heart failure is direct injury, excluding, of course, external wounds, as, for instance, the very rare occurrence in which a healthy man, during some sudden effort, ruptures one of his aortic cusps. The whole cardiac mechanism is suddenly put out of gear, severe præcordial pain disorderly action and faintness ensue, to be followed by other signs of perturbed circulation. In the only case of this injury that I personally remember seeing, almost immediately there was a smart hæmoptysis, no doubt from the over-distended left ventricle obstructing the return from the lungs. Under the only treatment possible—very complete rest—the heart, at first surprised and only very imperfectly able to deal with the altered mechanism consequent upon the spoiled condition of its main valve, gradually steadied down. The left ventricle enlarged and increased in power, and a small, rapid and irregular pulse was gradually altered to that having the characteristic features of aortic regurgitation. This alteration of pulse marked the adaptation of the heart to its new conditions in a manner precisely similar to that which we observe in a case of aortic regurgitant disease, in which dilatation of heart and mitral inadequacy having arisen, the irregular mitral characters of the pulse change under rest and treatment to those proper and normal to a well-compensated aortic regurgitation.

The displacement of a clot from a systemic vein is a common cause of acute anginal heart failure and is attended with urgent dyspnoea, an irregular, fluttering pulse and very variable heart signs. The condition is indeed one of *asphyxia* of the heart, and it either terminates rapidly in death or the clot is further dislodged and propelled into the lung, when the cardiac symptoms quiet down and those of another order commence with hæmoptysis significant of pulmonary infarction. Here again we can only recognise what is happening and relieve suffering and ensure quietude by tubcutaneous morphia. Be it remembered, however, that these cases are by no means necessarily fatal; if the clot passes on to the lungs recovery ensues in a fair proportion, and the prognosis in each case must be considered on its separate merits.

Next to such injuries to the heart, of which I have given right-sided and left-sided examples, we must glance at cardiac failure from over-taxation.

There are two factors always at work, although in

(a) Delivered before the West London Medico-Chirurgical Society on Friday, June 21st, 1901.

different proportions in different cases, in producing cardiac failure from great or prolonged exertion, viz., direct fatigue of the nervo-muscular tissue of the heart and a poisoning of the blood of autometabolic source.

Speaking of young people and healthy hearts, acute cardiac distress is, of course, very common in these days of athletic competitions, strenuous school exercises, hard bicycling, &c. It is indeed surprising that actual heart failure so rarely occurs; but few of us have an opportunity of witnessing such an attack. Fatal cases are rare but have been recorded, but for the most part we can only observe the after effects of incomplete heart failure.

While gentle exercise calculated to raise the blood pressure within the coronary circuit is thus to be advised, caution is necessary that no cardiac fatigue be induced. The periods of exercise should be of short duration. In old people with atheromatous vessels, cramp in the legs is readily induced by any fatiguing exercise, in consequence of the imperfect nutritional change allowed by the narrowed arteries, and similarly we may get cramp in the heart muscle, that is apt to prove fatal. It is also to be noted that the cramp of fatigued muscles does not necessarily come on at once, but is frequently postponed until the night. Many a fatal attack of angina pectoris has thus been prematurely induced by some over-fatigue or excitement in the day.

Among the concomitants of heart disease or failure during violent exercise, as running, vomiting is one of the most common; a boy will tell you that at the end of a long race which has over-taxed him, he will cast himself panting upon the ground and vomit.

Among the after effects one of the most constant is anæmia, and both of these phenomena—vomiting and anæmia—may be regarded as bearing witness to a changed condition of the blood consequent upon the accumulation of products of metabolism which takes a not unimportant part in the mechanism of heart failure. I would remind you that gastro-intestinal attacks, vomiting or diarrhoea, are not uncommon occurrences in those who, habitually leading a sedentary life, suddenly take to exhausting exercise. There are other more certain proofs of altered blood in those who have died from excessive exercise and in hunted animals, of which increased liquidness of the blood, absence of post-mortem clotting and darkened colour are among the more obvious.

In estimating the consequences of over-taxation of the heart from violent or prolonged exertion, in young people especially, there are one or two points of practical moment to be observed. A glance at Beneke's (a) tables will show that the heart of the child is somewhat precociously developed. According to Beneke, whilst the height doubles in the first seven years, the heart volume increases nearly five fold. In the second seven years things go more quietly, the height increasing by one-third and the heart volume by one-fourth, but the practical effort of this developmental activity must continue on through these years.

This cardiac precocity is in accordance with what I believe to be a fact which I have long observed and pointed out in clinical teaching, viz., that the heart of the child—say between six and twelve years—is relatively hypertrophied, i.e., the apex beat is somewhat to the left of the normal and the impulse relatively strong. This is the case especially with boys, and, in my experience, holds good with a considerable proportion of them. I have regarded it as due to the ceaseless activity of children and to a developmental precedence of heart to chest and lung

capacity. The practical point is that I do not regard a slight extension of the apex beat within the nipple line, unaccompanied by confirmatory signs, as necessarily a morbid condition in a child. I look for the evidence of cardiac overstrain rather in an extension of the upper margin of dulness in the mid-sterno nipple line with an unduly perceptible beat at the ensiform base, and a hesitating action of the heart, i.e., an irregularity in rhythm and force. These signs in association with languor, anæmia, breathlessness on exertion, and sometimes a sharp pain at the heart which I have heard described as a "beastly pain catching the wind," caused by a slight effort, are sufficient for diagnosis. You may get others, such as murmurs: you often do get a hæmic murmur over the pulmonary area, but murmurs are by no means essential, or to be expected.

A cardinal point—and the only one I shall touch upon—to be borne in mind with regard to young boys and girls is their special aptitude for short spells of active exercise, but their complete unfitness for prolonged, fatiguing, monotonous exertion. This is almost the reverse condition applicable to older people, and it is one often forgotten, not perhaps so much at schools as at home. Athletic fathers, robust elder brothers, proud of the sporting alertness and eagerness of young boys, will often keep them out on long bicycle, golf, or shooting expeditions, and may thus cause grave damage to the young and rapidly developing heart.

The treatment of acute failure of heart from over-strain involves a period of a few weeks' complete rest and often many months of careful supervision. Young people make a rapid and generally a complete recovery, provided no actual lesion has been produced. The younger they are the more ready and complete the recovery. In youths and young men a degree of irritability of heart is often to be observed for many months, even for some years, the patient suffering from attacks of palpitation and cardiac pain on slight fatigue or exertion and often at night. Quiet exercise must be resumed after a time, and it is, in my opinion, better to allow interesting exercises, within measure, such as croquet, level cycling, golf and easy tennis, rather than more formal courses of training. But each case must be considered on its merits. In some cases of cardiac overstrain in young people it will be found that a feeble lung capacity has led through imperfect pulmonary circulation to the heart distress. In such cases well ordered respiratory exercises will best help the heart by developing the lungs and fortifying the thoracic aspiration in aid of the circulation. Well-planned sea voyages or sailing trips from the coast are peculiarly advisable for adults, provided strict injunctions against smoking and all strong alcoholic drinks are given.

Another form of fatigue heart failure is that frequently met with in acute disease. It is too long a story for me to go fully into now. I have dealt with it with some minuteness elsewhere, (a) as met with under one of the most common of circumstances, viz., in acute pneumonia. It is met with also in enteric fever, in acute bronchitis in old people, during a severe asthenic paroxysm and in other conditions, such as functional tachycardia. The heart failure in these conditions may come about with a gradual quickening day by day of the pulse until it becomes fluttering, confused, running, representing little more than peristaltic movements of the heart. In other cases, and this more commonly in plethoric, fleshy large-framed people, with a pulse at first not unduly quick, with considerable tension and accentuation of the second sound, the failure occurs quite

(a) "Die Altersdisposition," 1879, p. 94.

(a) Lumleian Lectures. "On Treatment in Diseases and Disorders of the Heart," Lecture iii.

suddenly, attended with rapid breathing, pallor and cyanosis, sweating; collecting mucous rattles in the chest and almost imperceptible running pulse. Under strong stimulation and the subcutaneous use of strychnine, the patient may rally and all the conditions improve, but relapse often, and in elderly people almost always takes place. An attack such as I speak of occurring in an old person with bronchitis or pneumonia is almost of fatal augury; the senile heart cannot recover the fatigue, and hence when the pulse mounts up to 120 in old people recovery is rare, unless the rapidity be attributable to functional disturbance from some temporary cause. With a sound heart in younger people no condition is too desperate for possible recovery.

Now to discuss the treatment of heart failure under these varying circumstances would be to discuss the whole management of the illnesses in question. There are a few factors, however, in special concern with heart failure in acute disease, which should be looked for as indications for treatment, viz., (1) maloxxygenated and otherwise contaminated blood supply to heart muscle and nerve; (2) excessive weight of blood burdening the heart; (3) exhausted innervation from sleeplessness and physical cardiac fatigue; (4) positive obstruction to the flow of blood through the lungs; and (5) changes in the texture of the heart muscle incidental to the disease and especially to the pyrexia. Now the first two indications are undoubtedly met by depleting the blood volume from the venous side by attention to secretions, the occasional use of mercurials, careful limitation of the food taken in place of the over-feeding often to be observed, and in some cases a small blood-letting. The timely employment of oxygen inhalations at intervals through the day is a remedy of great value which ensures an improvement in the aëration of the blood sent to the left ventricle, and so direct to the coronary vessels. It is by no means necessary to employ oxygen inhalations in the majority of cases of pneumonia, of which disease I am now especially speaking, but in all severe cases the cylinder should be at hand to anticipate the threatened heart failure.

No. (3) and (4), exhausted innervation and pulmonary obstruction are met with in pneumonia, advanced typhoid and asthenia especially. Strychnia is the most powerful cardiac tonic we know, and subcutaneously used is the best remedy for heart failure. In these cases, however, a frequent concomitant symptom is ballooning of the abdomen, and it is both dangerous and inefficient for the purpose required, to give strychnia in such cases by the stomach. In asthma, pneumonia, and in enteric fever, it is often possible in combination with the free use of oxygen and the occasional injection of strychnia to give a sufficient subcutaneous dose of morphia to procure much-needed sleep. When the heart threatens to fail in asthma the paroxysm must be thus shortened. In bronchitis, on the other hand, under no circumstances can morphia be so given. I have often observed cardiac exhaustion threatened in asthma through the want of small administrations of concentrated and assimilable food essences at intervals to support the patient. Alcoholic stimulants are, of course, often necessary, the dose being adapted to suit the individual case. (5) The changes incidental chiefly to pyrexia in the heart muscle as a cause of failure are mostly to be considered in the prolonged fevers and will be best warded off by a judicious mitigation of the pyrexia. I would only observe on this head that in cases where there is labouring action of the heart and a tendency to cyanosis and stagnation of surface blood, I have observed much better results from hot water than from cold water sponging or cold applications. The surface circulation is more facilitated, heat is rapidly

lost and the skin functions encouraged, all tending to lighten the burden of the heart. In the after treatment of pyrexial diseases, in which there has been prolonged rapidity of heart or any sign of heart failure, a chief regard has to be paid to restoration from cardiac fatigue. Thus our level sea and country resorts are preferable to hilly places, and exercise can only gradually and tentatively be resumed.

I can only glance at specific poison failure of heart in diphtheria, phosphorus poisoning, malignant anæmia and the like, in which the cardiac nerves are directly poisoned, and in most cases a rapid fatty change in the heart fibres ensues. These cases are mostly fatal with the exception of the influenzal cardiac affections among which symptoms of slowing and increased rapidity of heart are met with, also some most intense forms of angina, usually vasomotor, and attacks of dangerous syncope may occur, yet the prognosis is, even in severe cases, so far as my experience goes, as a rule, favourable.

Of angular heart failure I have no time to speak at length. I would only urge that from a treatment as well as from a scientific point of view, we must regard angina pectoris as in the largest class of cases a functional disease—a cardio-vascular neurosis. In many cases it is dependent upon disorderly action of the vasomotor nerves, and is associated with a sound heart (*angina pectoris vasomotoria*). In many other cases we have a similar mechanism, but with, in the background, an unsound heart—aortic regurgitation, aneurysm, senile fibro-fatty hypertrophy, coronary disease and the like (*angina pectoris gravior*, or secondary cardiac angina). In numerically a comparatively small class the angular failure is the consequence of cardiac degeneration, secondary to coronary disease, sometimes to coronary thrombosis or syphilitic disease, viz., syncopal angina or primary cardiac angina.

It is obvious that all the causes of excitement, direct and reflected, of the sympathetic and vasomotor nerves must be looked into in dealing with the larger proportion of these cases, whilst on the other hand, any special form of cardiac lesion must be appropriately dealt with. In accordance with what has been above stated, the immediate remedies for the cardiac attacks are, in the majority of cases, of the antispasmodic and sedative class, amyl, trinitrine, opium, directed against the arterial spasm, which is so important a factor in the attack. When we are assured of the presence of coronary lesion, the employment of regulated exercises, combined resistance and respiratory exercises, and, in old people especially, the regulated use of oxygen inhalation will help to maintain cardiac nutrition for at least a time longer.

There are two conditions leading up to heart failure which I have not touched upon, and yet which, from the remedial point of view are of immense importance, but they have been fully handled by my colleague, Dr. Mitchell Bruce, in his recent Lettsoman Lectures. One is typified in the middle-aged, plethoric man who, working hard, lives too well and takes little exercise. This man gradually acquires a fatigued and over-burdened heart, over-weighed with the heavy volume of blood it has to propel. He may get a spring or summer cleansing once a year at Homburg, Harrogate, or Carlsbad, with no intermediate precautions he drifts along often into irremediable disease of heart, or kidneys, or both. His first introduction to the physician is often after an attack of breathlessness and cardiac excitement, or failure occurring on some unwonted exertion, after which he remains perceptibly short-breathed. His cardiac area is extended, partly from a slight yielding, but mainly from præcordial and interstitial fat. The first sound is weakened often to extinction, the

second sound labouring; there may be slight albumen or a little sugar in the urine. If taken in time and placed under fluids taken chiefly between meals, a great curtailment of alcohol and smoking, and well arranged exercise, with insistence on deep, full inspirations from time to time whilst walking in the fresh air, such a man will be restored to health and practically rescued from some early catastrophe in the form of heart failure, in acute illness, or from drifting into chronic cardio-vascular disease. A few weeks' change away whilst getting inured to the treatment is of great value, and such cases will derive especial benefit from Nauheim or modified Oertel treatment.

The other class of cases I would refer to in association with two causative factors, viz., nicotine and epilepsy. I may bring my remarks to a point and a conclusion by a brief sketch of a case in illustration.

A captain in an infantry regiment was invalided home from South Africa, on account of attacks of heart failure. He was a married man, *æt.* 37, had never had syphilis, but was an inveterate cigarette smoker, and a little free with alcohol. In July, 1900, while mounting a hill he felt distressed, and on return to camp fainted, and after this he was unable to exert himself without some distress. In September, having escorted some prisoners from Durban to Cape Town, without sickness or fatigue or any hardship, he on arrival was about to get ready for dinner and in the act of taking a glass of wine bitters, when he suddenly fell down unconscious and pulseless, so that a doctor who saw him immediately thought him dead. He remembered nothing until he woke at 2 a.m., feeling very faint and ill. There was no preceding sense of faintness, no pain and no convulsion. On a later occasion, while feeling very well he suddenly fell unconscious for a quarter of an hour. He has had one similar attack since his return home in November. He was subjected to a course of Nauheim treatment without benefit. His complaint was, besides these attacks, of almost daily attacks of cardiac pain, especially induced by any exertion. Dr. Walker, under whose care he came subsequent to the Nauheim course, by rigorously restricting the tobacco and regulating his diet and stimulants, materially relieved these symptoms, and when I saw the patient with Dr. Walker in April the cardiac dimensions, position and sounds were normal, and the pulse, although feeble and rather quick, presented no other special feature. On inquiry into this gentleman's family history nothing cardiac was elicited, but it was ascertained that his brother was a deaf mute and his second son was the subject of very frequent and severe attacks of *petit mal*. This case was primarily, no doubt, one of angina heart failure in association with excess in nicotine, and as such belongs to a class of frequent occurrence, but the instantaneous attacks of unconsciousness were suggestive of at least an associated neurosis of an epileptic character. I have met with one other very strikingly similar case in a younger man, also an excessive smoker, and I have a less full recollection of another case in connection with excess in cocaine.

I have from time to time been consulted about a lady who has long been the subject of night attacks of an epileptic character, and who has recently developed marked and rather severe attacks of angina, with heart failure of an alarming degree, many of which attacks usher in a mild epileptic seizure. In her case the pulse of late years has become extremely slow, and she has presented some symptoms of myxœdema. It is remarkable that in this case the amyl class of drugs are useless, but strychnia gives immediate relief both to epileptic and cardiac phenomena.

Cases of cardiac hesitation with pulse of uneven

rhythm, not amounting to intermittency and presenting occasional attacks of fainting, are not very infrequent among children, young boys, especially between the age of six and puberty. They are easily tired, and are generally anæmic. It is quite exceptional to find them addicted to any secret vice. There is nothing abnormal beyond altered rhythm and vacillating force to be found in the heart. The distinction between this form of heart failure and *petit mal* is often difficult, and I am strongly inclined to regard the two conditions as allied. Removal from any mental pressure, an outdoor life and arsenical tonics, generally result in gradual recovery.

I have endeavoured in this address rather to suggest lines of thought and methods of treatment, feeling that you are as competent as I am to give a practical therapeutic interpretation to whatever of my suggestions may meet with your acceptance.

### THE "MONOMA." (a)

By HERBERT SNOW, M.D.Lond., &c.,  
Senior Acting-Surgeon, Cancer Hospital, Brompton.

I HARDLY think any one will dispute the claim of our former President, the late Mr. Lawson Tait, whatever may have been his personal defects, to be regarded as the most original and brilliant gynecologist of modern times. One of his most important contributions to that science seems to me in some risk of oblivion, at least, I do not remember any allusion to the point since the publication of his work. And although the case I have to report was unfortunately not successful, I feel sure that apart from its own intrinsic interest, the Society will approve of anything tending to rescue a question of much practical significance from unmerited neglect.

It will be remembered that Lawson Tait's experience led him to distinguish, and to insist strongly, on the clinical difference between two species of uterine myoma. He laid down two fundamental distinctions to begin with. The ordinary prevalent fibroid tumour is generally multiple when first encountered; and, if not, speedily so becomes as time advances. The rarer, the "soft œdematous myoma," is invariably a solitary tumour, and remains single to the end. In the second place, while the former may never attain any considerable size, and may even diminish in bulk after the menopause; the latter always steadily continues to increase until the patient is "released by art or removed by death." That is to say in other words, while the common myoma is a benign new growth the rarer "soft œdematous myoma" is one truly malignant.

Then Lawson Tait further drew certain minor distinctions, into which I am not sure we can unreservedly follow him. Thus he stated that removal of the appendages promptly terminated the growth, and the attendant menorrhagia of the common myoma, while that operation had no effect on the rarer variety. The former arises only during the menstrual epoch, the latter prefers the old, though, as in my own case, it may begin earlier. The ordinary myoma tends to diminish in bulk after the climacteric; the latter is wholly unaffected by this. The former often involves menorrhagia; the latter is rarely attended by undue loss of blood per vaginam, and has no influence whatever on the menses.

One of Mr. Tait's cases ultimately involved a livid protrusion through the umbilical aperture. I had an opportunity of examining microscopic sections from two others. One showed only non-striated muscle-fibre; the other, the abundant nuclei and small spindle-cells which denote a myo-sarcoma. In

(a) Paper read at the British Gynecological Society, June 18th, 1901.

such matters, as I have often insisted, the clinical evidence of malignancy is far more trustworthy than the report of a microscopist who has never seen the case. The malignant process is commonly limited to certain areas, which may be neglected when a thin section is cut for the microscope; or may escape notice even when therein included.

The following is a brief note of the case in question:—

Lucy J., *æt.* 47, married, but for several years separated from her husband, was admitted into the Cancer Hospital, November 27th, 1900. She had previously, in 1895, undergone an operation there for cystic degeneration of the mamma. Since then there had been menorrhagia. There had been one child born at full term, one miscarriage, one premature birth. Had noticed enlargement of the abdomen one year. Has lost much weight in the past eight months, though still stout and rather flabby-looking. At the menstrual periods there is much pain, but that has always been the case. The loss, however, is "like that of a confinement."

The abdomen was found distended by a central round mass, mobile, exhibiting ill-defined fluctuation like that of a tense cyst. A consultation of the staff was held according to rule, and while the majority regarded the tumour as solid the possibility of a thick-walled ovarian cyst was admitted.

Abdominal hysterectomy, after Dr. Heywood Smith's method, was performed on November 30th. The divided cervix proved exceptionally vascular. On the following day all was well, as the temperature chart sufficiently indicates. There was no vomiting, and not even a headache. And here I cannot forbear quoting the acute remark subsequently made to me by the excellent nurse in charge of the case, that "she was always better pleased when they vomited well after an abdominal operation, for otherwise it seemed as though they had to get rid of the bile afterwards, and were thus thrown back."

On the morning of the second day an enema of glycerine and peppermint water was given according to my invariable rule, and the bowels acted freely.

On the afternoon of the third, going into the ward, I found that the abdomen was distended and that the patient was vomiting. Another enema was immediately ordered. The bowels acted, the patient passed flatus, and felt much relieved.

At about four o'clock on the following morning, however, she again began to vomit, and this time the ejecta were *fecal*. I was sent for at eight. Another enema was administered, and preparations were made for re-opening the abdomen. The patient, however, sank rapidly, and died at 12.30.

At the autopsy was found enormous distension of the stomach and intestines; with two perforations of the ileum about ten inches above the ileo-cæcal valve. The peritoneum was perfectly healthy, and all the surgical conditions in every way satisfactory. No adhesion, kink, or other source of obstruction could be detected. There were three inches of fat on the abdominal wall; a condition pointing, I think, to rather free indulgence in alcohol, which I regard as militating strongly against recovery in such cases.

It must surely be an almost unique event for a not aged woman to go on for several days after a *cœliotomy*, having her bowels well moved more than once, and then to collapse suddenly from intestinal distension and rupture, without any mechanical source of obstruction whatever.

The microscopic section exhibited shows, over almost the whole area, the organic muscle-fibre of an ordinary myoma. A very minute region, however, displays the heaped-up leucocytes and abundant cell-proliferation denoting a cancerous degeneration.

Apart from the very unexpected and peculiar ending, I should direct the Society's attention to the following points:—

I. The existence of this progressive and malignant growth, for which I venture to propose the new term, "Monoma."

II. The importance of differentiating it from the comparatively harmless myoma, by this or some other distinctive word. For, here, there can be no question of tentative measures or of delay. The disease is malignant, and once recognised should be immediately removed.

III. The important question of diagnosis, hitherto neglected, and as yet unsettled. The presence or absence of vaginal hæmorrhage, as insisted on by Lawson Tait, is untrustworthy. With that event alcoholic habits have much to do. Age also is an uncertain factor.

If we encounter a solitary rounded, *doughy*, central uterine tumour which is growing rapidly, while the patient is losing weight, if we find an indistinct fluctuation, so that we doubt whether it is not an ovarian cyst we are dealing with, and if there has been much recent trouble and anxiety, then I hold we are justified in diagnosing a Monoma, and in advising prompt excision.

To the naked eye the tumour will, after removal, present a superficial resemblance to the common benign form. But its solitary condition, if any size has been reached; the division of the cut surface into lobules, between which are connective-tissue trabeculae infiltrated with serum; the presence of soft areas, into which one can easily push one's finger; the greatly hypertrophied uterine wall, simulating pregnancy; differentiate it.

Under the microscope the malignant portions will show very numerous leucocytes, with cancerous proliferation of the muscle-nuclei; while the non-malignant will display only the phenomena of well-organised muscle. But here special supervision must be exercised over the proceedings of the pathologist. Otherwise the section will probably be taken from the tough, well-organised areas; while the softer and more vascular, upon which the accuracy of his report will mainly depend, are prone to escape. I fancy the thin section here exhibited, and over the cutting whereof no such supervision took place, will exemplify the error which might so readily arise. For you see only a very minute portion of malignant tissue at one edge of the section, its bulk being composed of well-organised muscle-fibre.

## TWO CASES OF SYPHILIS WITHOUT PRIMARY LESION.

By Dr. L. JULLIEN,

Surgeon to the St. Lazare Hospital, Paris.

CLINICAL experience sometimes throws more light on morbid processes than experimental observation. The cases which I am about to relate are in contradiction with generally received views, but they are so well authenticated and so unquestionable, so closely in accord moreover with modern ideas on the evolution of the virus, that we can only bow to facts and record them for the benefit of our theories.

On June 9th, 1899, two medical men, a surgeon and his assistant, operated on a woman for a præsternal tuberculous tumour. After excising the tumour and scraping the base, they proceeded to insert the sutures. The needle did not work very well, and the surgeon, in endeavouring to withdraw it from the edges of the incision, ran it deeply into the end of his index finger. The needle being flat, with sharp edges, made a rather extensive wound which bled freely. His assistant, in

repeating the manoeuvre, did exactly the same thing and wounded himself in the same place. On June 17th, on changing the dressings for the first time they noticed a slight ulceration with bright red edges at the orifices of entry and exit of each suture. These appearances suggested the idea of syphilis, of which nothing in the patient's history had previously transpired. On the following day she developed a generalised roseola, and on examining the genital organs they forthwith discovered a syphiloma in the region of the fourchette, undergoing cicatrisation. The inguinal glands were enlarged.

On July 5th, twenty-six days after the inoculation, the surgeon was suddenly seized with fever, shivering, and a general feeling of discomfort, and kept his bed for twenty-four hours with a temperature of 39° C. (102.2° F.). At the same time the site of the puncture became painful, the end of the finger became swollen, and the scar of the puncture displayed a tendency to reopen with some trifling superficial ulceration. On the thirtieth day a roseolar eruption made its appearance. On July 16th the scrotum became covered with moist papules, and two days later *plaques* formed on the tongue. He then began to complain of arthralgia, which, throughout the month of July, rendered the loins and wrists painful. On the 26th we noted palmar papules, since which time the disease has followed its implacable course, though in a mild form.

The assistant displayed no sign of infection until the thirtieth day, but on July 9th he, too, was seized with fever. Nothing abnormal was at any time noticed at the site of inoculation, the scar whereof remained intact, and the roseola did not appear until the thirty-third day. I need not go into the details of the subsequent history of the attack, which followed the usual course. I wish, however, to insist particularly upon the conclusions which we are justified in drawing from these data, conclusions which are fairly obvious.

1. The blood of a syphilitic subject is infective, a fact with which Pellizzari had already acquainted us, but we did not know for certain the epoch at which it becomes infective. The present observations prove that the infectivity exists prior to the occurrence of the secondary symptoms, since the surgeon and his assistant were inoculated nine days before these made their appearance in the patient. Assuming an average period to have elapsed between the primary lesion and the secondary symptoms, the patient must have had her chancre some thirty days before.

2. In these two cases the inoculation accidentally took place into the blood itself, and the evolution of the disease skipped the stages which usually give time for a focus of infection to develop at the point of inoculation, giving rise to a syphiloma, thus impregnating the lymphatic system, which is always the first to suffer. Here the lymphatic period is done away with, the organism is taken by assault, without being enabled to avail itself of the glandular barriers, which are swept aside from the onset. As a matter of fact our *confères* sought in vain for evidence of glandular enlargement in the areas corresponding to their wounds. The glands only became perceptible at the period of efflorescence, concomitantly with the mucous manifestations, whence the early supervention of the constitutional manifestations.

This mode of invasion of syphilis, which was theoretically studied by Professor Oltramare, of Geneva, and was clinically demonstrated by Verchère, of Paris, who only succeeded in obtaining the recognition of his cases with considerable difficulty, has never, to my knowledge, received such conclusive confirmation. I need hardly insist on the

far-reaching importance of these observations both from the purely practical and scientific points of view, and I thank my unfortunate *confères* for having permitted me to take careful notes of the details.

## SYPHILIS AS A NON-VENEREAL DISEASE: WITH A PLEA FOR THE LEGAL CONTROL OF SYPHILIS.

By L. DUNCAN BULKLEY, A.M., M.D.,

Physician to the New York Skin and Cancer Hospital; Consulting Physician to the New York Hospital, &c.

ADVANCING civilisation has recognised one after another of the contagious or infectious maladies which afflict mankind, and the arm of the law has come in to protect the defenceless, and we no longer have the wholesale sweep of epidemics which occurred before health boards were organised and given control of these matters. This is often accomplished at the sacrifice of the comfort and, it would often seem, the rights of individuals; but the principle of the "greatest good for the greatest number" prevails, and those who unhappily may become afflicted with any of the maladies coming under the jurisdiction of the health boards are often obliged to sacrifice all personal interest for the benefit of those around them.

Why is it that syphilis, which has always been recognised as an intensely contagious disease, in certain of its stages and manifestations, has, to such a great extent, been allowed to pursue its unbridled course, attacking alike the innocent and those guilty of sexual transgression? Why is it that thousands, yes hundreds of thousands of innocent and trusting wives and helpless and blameless children have had to suffer for the sins of others? Why is it that syphilis has thus been allowed to spread its ravages unchecked by the hand of advancing science and broad philanthropy?

I need not answer these questions, for I am convinced that all my hearers know full well the reason. But, thanks to the light of accumulated knowledge and experience, the shame which has too often checked discussions of the subject, and hampered the efforts of many who, from time to time, in various countries, have tried to stem the tide of this disease, need no longer have an influence. I hope to give you facts and show you reasons which will make every one present feel and know that the disease (syphilis) should and must now have a check put upon its ravages—and my plea will rest, as the title of my paper indicates, upon the vast "army of innocents" who plead for protection from a disease which may attack them when least expected, and may often extend its malign effects through years, and even to succeeding generations.

It is not a little interesting to note that when the disease burst out with such frightful severity in the years 1494 and 1495, at a date closely following the discovery of America, and about the time of the invasion of Italy by Charles VIII. of France, it was not by any means considered as a venereal affection, but spread so greatly among families and in neighbourhoods that it was regarded as a form of plague; many laws were therefore enacted for the protection of the community against what was considered as a new disease which had appeared among them. Also later, even in the sixteenth and seventeenth centuries, we find laws regarding those afflicted with syphilis, prohibiting them from the use of public baths, and even preventing them from coming into general assemblies, &c., and some of the measures taken to hinder the spread of the disease were harsh in the extreme.

I will not attempt, in any way, to go into the legal aspect of the case, either historically or practically, for time and space would fail me on an occasion like this; legal action will follow when once the public is convinced that there is a danger which can be thus avoided.

Mention was made of legal restrictions of the disease

exercised long ago, in order to call attention to the fact that when syphilis was regarded as a general malady not necessarily connected with the sexual act, there was great attention paid to its control; but now, in later years, since it has been regarded more and more as a venereal disease, it has been ignored and left to pursue its destructive way unchecked by sanitary control. The height of the folly culminated in the silly agitation in England which terminated in 1891, with the repeal of the "Contagious Diseases Acts," which had wrought such beneficent results from 1864 till 1881.

As already intimated, the pendulum of knowledge has swung the other way, and during the last twenty-five years or so, a mass of facts has been steadily accumulating, which again calls attention to the aspect of the innocent infection by syphilis, and which demands that the thoughts of those who make laws for the protection of the public shall be again turned to the disease. The data referring to this "Syphilis in the Innocent," the present writer has been collecting for the past ten years, and has recently embodied in a volume, to which further reference will be made in our discussion of the subject.

The basis of our present argument is as follows: as long as syphilis is regarded exclusively as a venereal disease, it is and will be extremely difficult to obtain adequate legislation for its control; whereas, if it can be shown to be one from which the general and innocent public should be protected, there will be little difficulty in meeting and solving the question; it is the hope of the writer that the present paper, with the discussion which may follow, will be the means of such agitation as will result in the ultimate adoption of laws which will in a measure control syphilis in this country.

In order, therefore, to properly understand and appreciate the task before us, it will be necessary to enter into some details in regard to the present extent of syphilis, its modes of propagation in times past, including many episodes which were called epidemics, on account of the large numbers innocently affected in a brief period, and finally to the modes of propagation of the disease in late years, by other than unlawful venereal acts. These matters I will endeavour to present as concisely as possible.

#### WORLD-WIDE DISTRIBUTION OF SYPHILIS.

A word first in regard to the general distribution of syphilis in the world. Many have written from time to time as to the antiquity of syphilis as a disease, even from the most ancient times, and bones exhumed here and there have seemed to show that it has prevailed for ages, as also records in Chinese literature point back to its existence at least 2,000 years B.C. But for practical purposes, most studies of syphilis go back only four hundred years to the period mentioned, 1494 and 1495, and as all know, it was charged that the followers of Columbus brought the disease to Europe from the western lands. Since 1494 the disease has spread, apparently *de novo*, until now, according to the best writers, there is hardly a portion of the inhabited globe where it does not exist with more or less virulence. It is stated that in Russia at least one-quarter of the inhabitants in some villages are infected, and all writers agree that there it is mostly spread in an innocent manner, mainly in family life, as will be mentioned later, for prostitution is almost unknown in the villages.

In Great Britain and Ireland it prevails widely in the great cities and ports, favoured by the neglect of all restrictions on prostitution. Dr. Holland in 1854 estimated that in the United Kingdom there were at least a million and a half persons infected with syphilis each year.

Japan and China are so full of it that Dr. Eldridge states that it is very exceptional to meet a male Japanese who will not acknowledge that at some time he has had syphilis, and in the French Hospital at Tien-Tsin, China, almost 30 per cent. of all cases were of this disease. Time fails even to touch on its prevalence in various other countries, but as stated before, syphilis exists almost universally, and, according to the best authorities, it is steadily on the increase.

There are no data to determine the extent of its pre-

valence in the United States, but any one familiar with dispensary and hospital work in this country will vouch for the very great amount of it seen in daily life. The statistics collected by the American Dermatological Association, relating to some 300,000 cases of skin disease, give a percentage of 11.5 due to syphilis. Some years ago Dr. Sturgis collected the returns from the public institutions in New York City, and estimated that the numbers newly infected there with syphilis could not be far from 50,000 each year.

Time would fail me even to hint at the mass of material which has been brought to light in regard to the modes and methods by which syphilis has been innocently given to individuals, even up to the present time, and often in spite of great care being exercised.

The three great classes or divisions of the subject to which I wish briefly to call your attention are: 1, marital syphilis; 2, hereditary syphilis; 3, extragenital, innocent syphilis.

#### MARITAL SYPHILIS.

The subject of marital syphilis has been very fully discussed by a number of writers, and all acquainted with the subject know well that this mode of infection stands prominent in connection with the innocent acquiring of the disease. While men occasionally contract syphilis innocently in lawful wedlock, even indeed from wives who have acquired it in nursing a syphilitic child, or in some other innocent manner, it is principally the wives who suffer, from the sins of their husbands, before or after marriage, and on them falls a large share of the burden of "innocent syphilis."

Fournier, of Paris, recently made some studies from the cases of syphilis coming to him in private practice. He found that fully 25 per cent. of all females whom he had seen in private practice had contracted the disease innocently and undeservedly, and in the discussion of his paper, Ricord thought that that proportion was too low. Of the married females in Fournier's practice, he found that in 75 per cent. of the cases the disease was unmistakably traced to the husband. In my own private practice I found that in fully 50 per cent. of the females the disease was acquired in a perfectly innocent manner, while among the married females the percentage of innocent infections would be 85 per cent., or more. Surely, then, there is reason in the plea that something should be done to prevent the wholesale infection of these innocent victims of marital syphilis. But if this aspect of the subject is dark, that of hereditary syphilis is yet darker, and calls even more strongly for relief.

#### HEREDITARY SYPHILIS.

The literature of hereditary syphilis is very large and the facts related to it are well known to the profession. Time and space will allow of but the briefest mention. We may for a moment first refer to the effect of the poison upon the viability of children born of syphilitic parents. I cannot do better than refer to some very striking tables given by Sturgis in an appendix to Diday's work on "Infantile Syphilis." They are from the records of births of syphilitic children at the Moscow Hospital, Russia, from 1860 to 1870. During these years there were 2,002 such births, and 1,425 deaths; that is, 71 per cent. of the children born there of syphilitic parents died. Other writers are in accord as to the very great death-rate among those born of syphilitic parents.

It is to be remembered also that syphilis is the cause of innumerable abortions, and also produces sterility, both in the male and female. If, therefore, the effects of syphilis were limited solely to destruction of life in the newly-born, or in the products of conception, there would be a strong reason for the introduction of measures to check the spread of the disease, from its loss of life to the state. But this is only a portion of the ills wrought by syphilis in connection with generation, and it would be better that children of syphilitic parents should thus fail of life, rather than be born with an inheritance which often proves a curse.

#### EXTRAGENITAL SYPHILIS.

The third division of our subject, namely, extra-

genital infection, or syphilis acquired quite apart from any sexual relations, is one of the most interesting lines of investigation possible, and has been illustrated by thousands of recorded cases, reported by many hundreds of observers. I may remark that nearly 200 cases of this kind have fallen under my own personal observation and care. A slight classification of the facts may help us to a better understanding of the vastness of the subject, and its very, or most, important bearings upon the health of the community and the dangers from syphilis.

The cases referring to the different methods of acquiring syphilis accidentally, apart from sexual life, as actually observed at the present time by every one who has opportunities and experience in this line, may be grouped under three main catalogues: 1. Those relating to domestic and industrial life. 2. Those relating to the nourishment and care of children. 3. Those relating to professional pursuits in the care of the sick.

Under the first class we find the instances of transmission finally classified into almost fifty groups, relating to the most different phases and aspects of domestic and social life. Not only has syphilis actually been given by spoons, knives, forks, cups, glasses and jugs, but it also has been communicated by tobacco pipes, cigars, cigarettes and even by troches or candy passed from mouth to mouth; also by shirts, drawers, masks, plasters, bandages, lint, towels, sponges, combs, tooth-brushes, syringes, sick-chairs, &c. Among those who have acquired it in industrial life, that is, innocently in connection with their occupation, we may mention glass-blowers, assayers, weavers, musicians, conductors (by whistles), servants, cooks, furriers, upholsterers, shoemakers, and others.

The second class, representing syphilis acquired through the nutrition or care of children, includes literally thousands of cases where the disease has been innocently acquired by suckling syphilitic children at the breast, and innumerable cases where the nurses and attendants have acquired it by contact with the syphilitic secretions of infants and where diseased children have communicated the disease to each other.

In the third class, relating to professional body service, in connection with the care of the sick, we find three divisions: (1) where the operator is the victim; (2) where the operator is the syphilitic, or gives it from himself to a patient; and (3) where the operator is the medium of conveying the disease from one patient to another.

Under the first class we find hundreds of cases where physicians, surgeons, and midwives have become infected in the practice of their calling. Large numbers of cases are on record where breast-drawers and wound-suckers have acquired the disease.

In the second class we find many records of those who have had syphilis giving the disease to others by body service, as in tattooing, circumcision, vaccination, &c.

In the third class the operator acts as a medium, conveying the poison from one patient to another. Here we find a sad array of cases of infection by skin-grafting, vaccination, through dental instruments, by wet-cupping, the use of the Eustachian catheter, &c.

#### LEGAL CONTROL OF SYPHILIS.

I have thus hurriedly, and necessarily very briefly, run over a few of the points relating to our subject illustrating the propriety of my "plea for the legal control of syphilis based on its frequency in the innocent"—the details necessary to a full understanding of it would take many, many pages, and occupy as many hours. I beg now to present a brief argument for, and a statement of the method and mode of, the legal control of syphilis which I think feasible at the present time.

From what has preceded it is readily understood that syphilis is a disease which inflicts great injury upon the public health; for it imperils not only those who have been guilty of sexual transgressions, but also those who are quite innocent, and it is upon the basis of protection for the latter that I believe action should be taken.

While syphilis occurs most frequently as a "venereal disease," its prophylaxis or legal restraint by no means

relates to the restriction of venereal diseases; the limitation of the spread of syphilis should be considered from a much broader and higher standpoint, namely, from that of defending the public health and that of individuals against a malady which affects the innocent and guilty alike, and which comes to the innocent not only when its dangers are anticipated, but also when they are least suspected.

In the matter of legal protection against syphilis, therefore, the subject of prostitution becomes a secondary consideration. The question is not one of "regulating prostitution," or of inspecting, licensing, or legalising the "social evil," or of protecting those engaged in it. We approach it from a higher ground, and seek to have some restriction put on a disease which is dangerous and communicable, and which might at any time attack any one in a wholly innocent and unexpected manner. That the spread of syphilis can be checked is self-evident, as has been conclusively proved by the fact that all the epidemics to which reference has been made were averted when the cause was recognised and sufficient measures introduced to prevent the further transference of the poison from one person to another. It is also abundantly shown in certain instances where foreign governments have in some places enforced stringent measures looking in this direction.

We know positively that the poison does not and can not develop *de novo*, but that it is always communicated from one individual to another. We know also that within a certain period syphilis ceases to be contagious in each individual; so that if no new infection is introduced into a community, and the members of that community are guarded against acquiring the disease from one already infected until that safe period is reached, the malady will cease to exist.

Such precautions are exercised both by the public and by individuals against other contagious diseases, such as small-pox, scarlatina, measles, diphtheria, yellow fever, &c., is it not eminently proper that syphilis should be placed in the same category, and protection should be afforded to the innocent against it? Syphilis counts its victims, guilty and innocent, by thousands where other diseases count hundreds. More deaths are ultimately caused by syphilis than by small-pox, while the injury to health, and interference with life work is infinitely greater in the former than in the latter. The conclusion is absolute: syphilis should be placed, like other contagious diseases, under the control of the health authorities.

The first step toward accomplishing such control would undoubtedly be found in placing it among other contagious diseases which come under the jurisdiction of the health officers; indeed, the wonder is that it has not been so placed long ago.

If syphilis were first recognised as one of the great contagious diseases, against which it is the duty of the government to protect the community, the details of that protection would follow in time, as they have in regard to other contagious diseases; as the public became aware of the dangers arising from syphilis, and the benefits accruing from its restriction, there would be no difficulty in securing proper laws relating to the subject. The suggestion, therefore, is most earnestly put forward that the time has certainly come when the dangers of syphilis, and especially the dangers to innocent persons should be fully and fairly recognised and met. It is too late in the history of science and of humanity to stigmatise the disease as "venereal," and on that account to withhold scientific protection from thousands of innocent sufferers. Among babies, nursing women, persons infected in dental and surgical operations, and in dozens of other innocent manners, syphilis can no more be described as venereal than can any other contagious disease. The time has come to place it under the control of the proper health officers, and to make it quite as *criminal to transmit syphilis wittingly*, as it is to communicate small-pox, scarlatina or diphtheria. It is believed that if only syphilis can be included on the list of contagious diseases which the health boards can control, proper legislation will follow slowly as the profession and public become more enlightened as to the real nature of syphilis and the real danger of the public from it.

## Clinical Records.

### VASOGEN IN THE TREATMENT OF SKIN DISEASE.

By DAVID WALSH, M.D.,

Hon. Physician, Western Skin Hospital, London, W.

THE value of a good excipient is so universally recognised by all dermatologists that there need be no apology for publishing the records of a few cases in which a new material of that kind has been used. Before making any trial of vasogen, with various preparations of which the following cases were treated, it was ascertained that actual absorption took place when rubbed for a long enough period into the skin. That property is specially desirable in cutaneous medication, and in the case of vasogen is attributed in part to its peculiar ability to form a stable emulsion with the secretions of the skin and of wounds, as it does with water. On the whole it may safely be said that the preparation is worthy the careful attention of practitioners who are called upon to treat diseases of the skin.

S. O., female, single, *æt.* 24, confectioner, complaining of a rash of several weeks' duration. There were scattered over arms and body a number of patches, fawn-coloured or faint pink; slightly scaly; a little irritating at times; growing rapidly from a small spot to (usually) a ringed round or oval patch the size of a shilling or a crown. Patient had a similar attack a year ago. The scalp was affected with a mild, dry seborrhoea. General health good except a little dyspepsia at times. The rash disappeared after about six weeks' treatment with vasogen, iodine, and creolin baths.

E. M., female, *æt.* 31, m., no children, complains of rash on hands of six weeks' duration; similar attack a year previously. Rheumatic fever in family. General health good. Three fingers of the left hand were in an eczematous condition, dry and desquamating, except one small patch, which was moist and excoriated, and one nail had been shed. The attack came on after washing and was diagnosed as a dermatitis, due to an irritant applied to a rheumatic subject. Under the application of a diluted vasogen iodine ointment (5ij. later increased to ʒiv. to the ʒj. of vaseline) immediate improvement took place. Some fresh crops appeared a month later, but at the end of two months the hand was cured. [The treatment of eczematous conditions by iodine certainly deserves further attention.]

E. G., female, *æt.* 41, m., five children, three miscarriages. Complaining of roughness and cracking of skin of palms for the last three or four years; hands have got well in summer, except this year. Has avoided soda in washing since the hands were attacked. At first the conditions improved under sulphur vasogen externally, and a soda and gentian mixture. After a month the patient was treated locally with mercury vasogen, and internally with a potassium iodide mixture. The hands then improved steadily, and were nearly well when patient ceased attendance at the hospital.

A. R., female, *æt.* 24, confectioner; all hair of head lost rapidly, and partially of eyebrows. Phthical family history and patient has had hip disease. The scalp was treated with a stimulant application of vasogen siccum with cantharides and ammoniated mercury. The patient volunteered the fact that the ointment disappeared after prolonged rubbing. After some weeks a growth of fine downy hair appeared over some parts of scalp, comprising about one-fifth of the total area.

E. S., male, *æt.* 52, clerk, has suffered for two years from an affection of palms. Five years ago he was treated for eczema of knees and leg. Good family and personal history. The palms showed a chronic desquamative dermatitis, extending slightly down the fingers and fading into healthy skin. Patient showed little progress under ordinary treatment, but has

improved steadily under vasogen iodine, and at the time of writing has a full prospect of recovery. [In other chronic palmar eczemas a similar treatment has proved satisfactory.]

### PSEUDO-TABES AFTER POLYNEURITIS.

By Dr. SYLLABA,  
Of Rennes.

I HAVE recently had under observation four cases of pseudo-tabes dorsalis after an attack of polyneuritis. This disease is sometimes known as "neuro-tabes peripherica" or "ataxic polyneuritis."

The first case was that of a compositor, *æt.* 62, with a gait of a gallinaceous or "stepping gait" and slightly ataxic; patellar reflex and Romberg symptom lost. On the other hand, the pupils were normal, and the sensibility of the large nervous trunks was quite intact, which justified the diagnosis of pseudo-tabes following an attack of polyneuritis, which came on with great pain in both lower extremities. The cause of the neuritis was due, I believe, to an advanced state of arterial sclerosis, which is not uncommon in the aged, and has been termed by Schlesinger, Oppenheim, &c., "polyneuritis senilis." It has, however, been objected that the vascular sclerosis could never reach such a degree as to produce pseudo-tabes.

My second case developed after an attack of typhoid fever. The patient, *æt.* 28, was a merchant, and four years ago suffered from a severe attack of typhoid, bleeding from bowel, three months' fever with frequent recurrences and great decubitus. All the limbs became paralysed, so that he had to be fed during four subsequent weeks. A year after the commencement of the fever the patient developed the gait of a gallinaceous, or "stepping gait," with paresis of the lower extremities and loss of patellar reflex. Electric treatment improved the condition, but has not cured it.

The third case was that of a diabetic female, *æt.* 40, who, during treatment for her disease, developed pseudo-tabes, followed, after the lapse of one year, by paresis of the lower extremities, distinct ataxia, and loss of patellar reflex. There is also extensive disturbance of the sensibility, with Romberg's symptom, which is not uncommon in diabetes, according to Williamson occurring in 50 per cent. of diabetics. The polyneuritis diabetica is not due to the hyperglycæmia, but rather to the toxic products of a morbid metabolism, which may resemble the acetone production, though not identical therewith.

The fourth case succeeded arsenic poisoning, which is not a common occurrence. After taking arsenic, sensibility in the extremities was affected. Along the course of nerve trunks the sensibility was greatly exalted, while the Romberg symptom was very prominent, the nails falling off and the patellar reflex disappearing. The most interesting point in this case is the "perverse dissociation," viz., that although the sense of touch was quite lost in both hands and feet sensation to pain and heat was quite intact.

## Transactions of Societies.

### BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD JUNE 13TH, 1901.

The President, MANSELL MOULLIN, M.A., M.B.C.P., in the Chair.

#### EXHIBITION OF SPECIMENS.

MR. W. H. NEWNHAM, M.A., M.B., physician-accoucheur Bristol General Hospital, showed a Fibro-myoma, which consisted of four distinct tumours, growing from one base, one of the four having become quite calcareous in parts. The patient, E. F., *æt.* 40, first seen in consultation with Dr. Perrott, was suffering from a large abdominal tumour which caused difficulty in micturition and defæcation. She had always had excessive hæmorrhage at the menstrual periods, but during the last three years this was accentuated and was accompanied by great pain. The uterine sound only passed three inches,

but the tumour completely blocked the pelvis. On February 21st, 1901, the abdomen was opened and the tumour removed by intra-peritoneal hysterectomy. Both ovaries were left behind, and the uterine arteries were not secured until the tumour had been removed. There was no hæmorrhage. The patient recovered without a single bad symptom, and left the Bristol General Hospital on March 18th, 1901, or twenty-five days after the operation. At the present date she is in perfect health.

Dr. MACNAUGHTON-JONES showed a specimen of Ectopic Gestation. The patient, æt. 30, had been nine years married; eight years since her last pregnancy, during which period the catamenia were quite regular up to November 24th, 1900. She had been treated on different occasions for retroversion of the uterus and prolapse. The symptoms of sudden, with periodical hæmorrhage, and violent pain, subsequently, and the formation of a large swelling behind the uterus, indicated ectopic gestation. Abdominal celiotomy was performed on April 1st, when a large adherent gestation sac of the right tube was removed. On bringing it through the enlarged abdominal incision a portion ruptured, allowing a quantity of horribly foetid and septic pus to escape. The peritoneal cavity was thoroughly cleansed out with weak formalin solution, and the edges of the wound wiped with a stronger one. Drainage by iodiform gauze was employed. From the symptoms, on the fourth day, it was found necessary to re-open the wound, when the peritoneal cavity was seen to be free of any accumulation, but the margins of the wound were infected throughout its entire extent, the slough being in the muscle and fascia. The patient died on the seventh day.

Mr. TARGETT had made a careful examination of the specimen, proving it to be one of tubal gestation, with a secondary sac between the gestation sac and the wall of the dilated Fallopian tube, in which the foetid pus had accumulated. This lay next to the bowel, with which doubtless it had formed adhesions, thus accounting for the infection. The gestation sac contained a fœtus corresponding with the stage of development at the end of the second month. The suppurating cavity represented that part of the dilated ampulla of the tube not occupied by the gestation sac.

Dr. MACNAUGHTON-JONES said that if such an accident occurred with him again he should feel inclined, having protected the bowel, to char the edges of the infected parietes with the thermo-cautery, and then make a clean section of the edges of the wound at either side before uniting it. In this case the peritoneum had clearly resisted the infection, which was limited to the parietal structures.

The PRESIDENT said that, when in an extra-uterine foetation the fœtus had become putrescent or any extravasated blood had become septic, the operation described by Dr. Macnaughton-Jones was almost invariably fatal. If the septic condition were recognised before operation, the vaginal route should be adopted, and the patient's life would then probably be saved. In the absence of evidence of sepsis, the operator naturally selected the abdominal route.

Mr. FURNEAUX JORDAN said that, no doubt, as Dr. Macnaughton-Jones had suggested, the adhesion of the sac wall to the bowel, and its becoming thin at that particular point, accounted for the infection of its contents. An interesting point, exemplified by this specimen, was that such a condition might remain quiescent for two or three months, or longer. The fœtus had evidently been discharged when the patient had the first attack of pain and hæmorrhage. Mr. Furneaux Jordan then described the following case, in which the history was very similar to that of Dr. Macnaughton-Jones' patient. A lady was twice cured in America for supposed retention of the placenta after abortion. She then gradually improved, and menstruated regularly for two years, when intense pain set in, in the abdomen. About ten days after its onset the abdomen became enormously distended, and the patient was found to have a high temperature. The swelling reached well above the umbilicus, and extended a little way into the pelvis, not, however, into Douglas's pouch. On opening the abdo-

men Mr. Furneaux Jordan found a sac embedded in adherent bowel and omentum. On separating the adhesions two pints of very foetid pus escaped. The fœtus corresponded in size to the duration of pregnancy prior to the abortion already referred to as having taken place in America. The patient, who was for some time in a very critical condition, ultimately recovered.

Dr. HAYWOOD SMITH asked if there were any indications, before operation, that suppuration was present, and further whether it might not be feasible to avoid putrescence by employing abdominal injections.

Mr. SKENE KEITH showed

FIVE SPECIMENS OF UTERINE FIBROIDS, THREE OF WHICH ILLUSTRATED IN A STRIKING MANNER THE VARIABLE RAPIDITY WITH WHICH THESE TUMOURS GREW.

The first specimen consisted of typical sub-peritoneal, intra-mural, and submucous growths, removed from a patient, æt. 28. Pain, fever, and hæmorrhage had necessitated confinement to bed during the six weeks preceding the operation. Four months prior to the removal Mr. Skene Keith had performed perineorrhaphy, and at that time there were no irregularities on the surface of the uterus, which he palpated without difficulty, and which appeared, from its size and consistency, to be subinvolved only. The second specimen, removed from a patient, æt. 34, had been discovered at the last confinement four years before the operation. The tumour which constituted the third specimen weighed eight pounds. It had been removed from a woman, æt. 28, and, although probably of only two years' duration, was far larger than the previous specimen. Interest attached to the fourth specimen because the patient had three years previously derived marked, though temporary, benefit from treatment by Apostoli's method. Failure to obtain permanent relief from electrical treatment was explained by the submucous position of the tumour. The tumour in the fifth specimen, removed from a patient, æt. 45, was of a fibro-cystic nature. The body of the uterus, which was shown, contained two polypi. The weight of the growth was 14 lbs. Commenting upon the exhibition of such specimens by an advocate of Apostoli's treatment, he said that the conditions had materially altered since he visited Paris to see Apostoli in 1887. At that time the published results in hysterectomy showed a mortality of over 30 per cent., or one death in three, though his father only lost one patient in twelve; but even with this lower mortality it was not considered justifiable to advise operation unless the patients were really very ill. The mortality to-day was less than 5 per cent.; though in some instances this figure was exceeded, e.g., at the Samaritan Hospital, where for the last two years there was a mortality of 10.6 per cent. At the same hospital the death-rate, after ovariectomy, for the same two years was 16.6 per cent., and in the year 1899, 19.6 per cent.

Dr. HODGSON, in comparing the abdominal and vaginal routes for operation, questioned the possibility of rendering the vagina permanently aseptic. It might be rendered temporarily so, but was liable to become subsequently infected from the rectum, or by discharges from the uterine cavity. He doubted the possibility of distinguishing by touch between the various internal organs, alluded to by Dr. Alexander in his paper, if adhesions existed. Referring to Dr. Alexander's statement that it was rarely necessary to employ sutures to close the vaginal wound, Dr. Hodgson said he thought that they should, at least, be employed to keep the edges of the peritoneal opening accurately together. In the majority of vaginal operations the operator was working in comparative darkness; and, subsequently, adhesions were much more likely to occur. These considerations lead him to believe that the abdominal route should be that of selection.

Adjourned discussion on Dr. Alexander's paper on  
POSTERIOR VAGINAL CÆLIOTOMY IN OPERATIONS FOR  
PELVIC DISEASES,

which was read at the previous meeting, and appeared in this journal on May 22nd.

Mr. FURNEAUX JORDAN (Birmingham) said that Dr. Alexander's paper was of peculiar interest to him, as he

had long advocated the adoption of the vaginal route in suitable cases. He did not regard the question as one of operation per vaginam versus operation per abdomen. Removal by the vagina was to be regarded as an additional method of treating disease, which, in certain cases, was devoid of many of the dangers attending removal by the abdomen. It was not possible to lay down hard and fast rules. The route adopted should be determined by such considerations as the relative sizes of the tumour, the pelvis, and the vaginal canal, the nature of the disease, and the condition of the abdominal walls. He approved of the use of the clamp to secure the pedicle of a cyst or a Fallopian tube, and had never seen harm result from its employment. He had in one case of acute suppurative peritonitis, in which there was such distention of the abdomen that breathing was seriously hampered, made an incision into Douglas' pouch without the administration of an anæsthetic. Three pints of pus escaped, but the woman, who was dying at the time, lived only a few hours afterwards. With the exception of this case, which was only technically a vaginal cœliotomy, though he had performed this operation over sixty times, not only had he no deaths, but he had never seen trouble follow. The patients were able both to get up and to resume work earlier than were those in whom an abdominal incision had been made, and did not have to wear a belt. These were considerations of importance to poor women. Lastly, the absence of an abdominal scar was an advantage should the patients subsequently become pregnant. The vagina could be rendered aseptic to the same degree and as easily as the abdominal wall, an opinion substantiated by the results obtained when the vagina was availed of for the removal of disease. Those who denied the possibility of rendering it aseptic should bring forward or quote cases in support of their contention. If those opposed on theoretical grounds to removal of disease by the vagina would give the method a trial they would be convinced of its value.

Dr. MACNAUGHTON-JONES said that the first point in selection of the route was the diagnosis. There must ever be a proportion of cases which could only be operated upon by abdominal cœliotomy, and others in which on every ground preference should be given to the vaginal route. The indications for and against one or the other had been times out of number discussed *ad nauseam*. Given a case suitable for operation by vaginal cœliotomy, whether we looked to the facility of operation or post-operative consequences, both in the risks and prevention of these, as also ready drainage when required, it certainly was the method for selection. This fact, however, in no way touched the advantages claimed for, and which were indisputably appertaining to the Trendelenburg method, in the greater control of parts, certainty in technique, and exposure of the operative field. He preferred ligatures to clamps in the vaginal operation.

Dr. ALEXANDER, in reply, said that he did not think proximity to the rectum a valid objection against vaginal cœliotomy. The field of operation was as close to the rectum in abdominal cœliotomy as in vaginal; in fact it occupied the same place. The vulsellum forceps effectually closed the os uteri, and provided against infection from that source during the operation. After the operation the vagina was packed with antiseptic gauze, which not only kept it sweet but drained away any discharge as it was formed. As to dealing with adhesions, they were as a general rule easily separated by the finger, and it was generally possible, by manipulating the speculum, to actually inspect the field of operation, so that we were really not working any more in the dark than in abdominal cœliotomy. Stitches were not necessary. The wound was closed effectually by the falling back of the uterus and the bladder, and the edges came together so accurately that there was no overlapping. Dr. Alexander was glad to hear that Mr. Jordan agreed with him as to the use of clamps instead of ligatures. The tissues to be dealt with were generally so soft that it was impossible to catch them and pull them down by forceps without running the risk of tearing them away from their attachments, whereas the clamps could be

applied without any such disturbance, and the prevention of hæmorrhage was certain. He did not agree with Dr. Macnaughton-Jones as to the ease with which a bleeding vessel could be found in these operations. The bleeding point in vaginal cœliotomy lies high up at one of the extremities of the broad ligament, and probably could not be reached and tied without opening the abdomen. It was therefore absolutely necessary that all possibility of hæmorrhage should be prevented at the time of the operation, and this was done most effectually by clamps. In vaginal cœliotomy, the possibility of hernia was completely avoided, and although the present method of performing abdominal cœliotomy guards more effectually than the older methods against its occurrence, still the possibility of hernia was always present, and in all probability took place much more frequently than surgeons admitted. He noticed that it was always the most recent method of operating that was supposed to prevent hernia. The truth really was that all methods failed, and that a considerable amount of time was required to show whether hernia would occur or not. In sloughing ectopic gestation such as the case Dr. Macnaughton-Jones had read, the vaginal route would certainly have been much safer, and although the sac could not have been removed by that route, still the dangerous contents of the sac could first have been drained with safety, and then the shrunken tumour could have been removed by the abdominal route. In fact this was the course adopted in a similar case described by Dr. Alexander in his paper.

Dr. HERBERT SNOW then read a paper on

#### SOFT ŒDEMATOUS MYOMA,

which will be found in another column.

Referring to this paper, Mr. CHAS RYALL, F.R.C.S., mentioned a case of "single soft myoma uteri," which he had removed by abdominal hysterectomy. *Case.*—D. F., surgical nurse, æt. 37, admitted into the Cancer Hospital suffering from a rapidly enlarging tumour of the abdomen. *History of present trouble.*—She had first noticed the abdominal swelling seven months ago, since when the abdomen has steadily enlarged, though there had been no pain until quite recently, and then only a slight dragging pain in the right inguinal region. The menstrual periods had become more profuse, lasting seven or eight days, and occurring every three weeks. There has been marked loss of flesh and strength, but no great anæmia. *On examination.*—A large, smooth, and solid tumour was found rising out of the pelvis and connected with the uterus. Bimanual examination showed a large mass projecting into the pouch of Douglas, and the tumour was found to have little mobility. A soft single myoma was diagnosed, and hysterectomy was recommended because of the rapid growth. *Operation, January 29th.*—The abdomen was opened in the middle line, and the uterus and tumour were drawn out of the wound with the aid of a myoma screw. After securing the broad ligaments, the uterus was amputated about the level of the os internum, the peritoneum was sewn over the cervical stump, and the abdominal wall sutured in three layers. The tumour was a soft single myoma of the sub-mucous variety, and occupied the posterior uterine wall. The uterine cavity was considerably enlarged, and the sound could be passed for six inches. The patient made an uneventful and uninterrupted recovery.

#### LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD JUNE 7TH, 1901.

The President, Mr. CRESSWELL BABER, F.R.C.S., in the Chair.

#### CASES AND SPECIMENS EXHIBITED.

Dr. F. DE HAVILLAND HALL showed a case of "Ulceration of the Larynx (? tuberculous)" in a man, æt. 48. There was no history of venereal disease or other previous illness. The affection commenced with loss of voice about twelve months ago, accompanied by cough and some expectoration, but no hæmoptysis.

There had been considerable loss of flesh, and there were signs of consolidation at both apices. Tubercle bacilli had been found in the sputum. He had been treated with iodide of potassium with but little, if any, improvement.

Dr. ST. CLAIR THOMSON considered the case one of tuberculous ulceration in a syphilitic subject, with which opinion Dr. de Havilland Hall concurred.

Dr. ST. CLAIR THOMSON showed a case of malignant growth of the larynx. The anterior four-fifths of the right cord was occupied by an oblong growth with an irregular mammilated surface. The anterior third of the left cord was also infiltrated. The point chiefly raised by Dr. Thomson was whether the whole of the right and the anterior third of the left cord could be removed without fear of stenosis.

Sir FELIX SEMON said that he had several times excised both vocal cords without any subsequent stenosis, and he thought the growth might be freely removed in this case.

#### THE EXTERNAL OPERATION ON THE FRONTAL SINUSES.

Dr. ST. CLAIR THOMSON also showed a case of frontal sinus suppuration fourteen months after the external operation, and

Dr. HERBERT TILLEY showed three cases demonstrating the result of the external operation. The completeness and permanence of the cure of the nasal suppuration due to frontal sinus suppuration, and the fact that the external scar was trifling and did not increase with time, were well illustrated by Dr. Thomson's case. Dr. Tilley's cases were shown to demonstrate that if the radical operation were effectively carried out, there was no reason why the recurrence of the discharge should take place with lapse of time, as had been suggested at a previous meeting. These cases had been operated on fourteen, nine, and six months ago, respectively, and there was still no trace of purulent discharge into the nostrils.

Mr. W. G. SPENCER asked what percentage of these cases was bilateral. He had noticed that most of Dr. Tilley's cases were unilateral, and he wondered whether this was due to the performance of an early radical operation on the one side preventing the empyema from becoming bilateral.

The PRESIDENT thought that the main point of interest was the exact radical operation which should be undertaken, and said the Society would be glad to hear the remarks of the exhibitors on the point. Two points had been clearly established: first, that an attempt should be made to stop the discharge by washing out the sinus from the nasal cavity; and secondly, that if radical operation were demanded, it was usually necessary to previously remove the anterior end of the middle turbinate.

Dr. THOMSON, in reply, said that in his case the anterior end of the middle turbinate was removed sixteen days before operation, by which efficient drainage had been secured. At the time of the operation the frontal sinus was found full of pus and entirely lined with degenerated polypoid mucous membrane. He had kept the wound open for eleven weeks, seeing that unsatisfactory results and even fatal cases had been put on record. Another factor in the treatment of his case was that the fronto-nasal duct had been cleared out but no drainage tube inserted.

Dr. TILLEY, in reply to Mr. Spencer, said that in twenty-three cases of frontal sinus empyema with which he had to deal, ten cases had been bilateral.

Dr. HERBERT TILLEY also showed two cases of thyrotomy for malignant disease of the vocal cords, in which the operation had been performed five and three years ago respectively. The patients were now in perfect health, and in one the voice was quite good.

Dr. FURNISS POTTER showed a case of infiltration of the left cord in a man, *æt.* 28, which was thought to be tuberculous.

Dr. MACKENZIE JOHNSTON showed a specimen of a cheesy mass found after removal in an adenoid growth. The mass was about the size of half an almond.

Dr. JOHNSTON also showed a specimen from a case of sarcoma of the tonsil with a microscopic slide. In this case an extensive external operation had been performed. By dividing the lower jaw and tying the external carotid, the whole disease had been got successfully away without marked hæmorrhage. The patient made an excellent recovery and was at present perfectly well.

Dr. DONELAN showed a sketch of an aneurysm of the aorta, in which paralysis of the left vocal cord was the only physical sign during life.

Dr. FITZGERALD POWELL showed a case of separation of the upper lateral cartilage of the nose in a male, *æt.* 25. The patient received a blow on his nose, which was followed seven months later by an abscess of the septum, which was opened and drained. From this time falling-in of the nose took place from the separation of the cartilages. He considered the case of interest as a comparison to one shown by Dr. Frederick Spicer at the previous meeting, which the latter considered to be due to the pressure of polypi.

Mr. W. G. SPENCER showed a case of chronic ulcer of the septum which, as it had lasted over a year and had shown signs of healing in parts and of extension in other parts he considered must be due to lupus or tubercle. Dr. MACKENZIE JOHNSTON, Mr. PARKER, and the PRESIDENT thought the ulceration was of a simple nature, and could see no signs of tubercle.

Mr. A. HUDSON showed an apparatus for vibratory massage which he had found beneficial in diseases of the eye and ear, and suggested that it might be useful in the pharynx and larynx for bringing about absorption of inflammatory thickening and for the stimulation of muscles in cases of paralysis.

Sir FELIX SEMON showed three cases of

#### BILATERAL ABDUCTOR PARALYSIS

in *tabes dorsalis*. In the first case the illness began three or four years ago with pains and "pins and needles" in the feet and "choking attacks" at night. Stridor at night was noticed three years ago, and for the last three months in the daytime also. On examination of the larynx, marked double abductor paralysis, almost complete, was found. There was inspiratory inward movement of the vocal cords. Tracheotomy became necessary.

In remarking on this case Sir Felix Semon said he wished to draw particular attention to the fact that since the performance of tracheotomy the inspiratory inward movement of the vocal cords had ceased. This fact he held to be important in connection with the question whether such inspiratory inward movements were due to a purely mechanical cause, *viz.*, to the rarefaction of the air below the obstruction during inspiration—a view held by the older laryngologists, and by the speaker,—or whether it represented an active inward movement of the vocal cords due to the fact that, during respiration both abductors and adductors were simultaneously innervated, and that the abductors having been paralysed, the innervation of the adductors alone prevailed. This view had been advocated by Rosenbach, Burger, and others. If it were correct, one would naturally expect the inspiratory movement to continue even after the performance of tracheotomy. The disappearance of the movement in the present case was held to point strongly in favour of the mechanical theory.

In the second case the illness began three years ago with a heavy feeling of the feet. About five months ago the patient first had choking attacks at night. The larynx showed abductor paralysis on both sides, with paresis of the internal thyro-arytenoid and the inter-arytenoid muscles. In Case 3 the illness began with gastric and rectal crises two and a-half years ago. Ten months ago the patient had choking attacks at night, and soon after noticed the change in his voice. On examination of the larynx considerable bilateral and asymmetrical abductor paralysis was found.

## HYPERPYREXIA.

At the June meeting of the Société de Pédiatrie M. Guignon reported a very interesting case of hyper-pyrexia occurring in an infant, the temperature running up to 109.4° F. without any appreciable cause. If anything the child's stools were too frequent and too large. After a few days the child died, and the autopsy revealed a large collection of faeces in the sigmoid flexure of the colon.

The question naturally arises, What caused the hyper-pyrexia?

Up to the time when the child's bowels commenced to act rather freely the child complained of no inconvenience or pain, and when a gradually rising temperature called for examination there was nothing found that could account for it. Even on making the autopsy the viscera were found to be quite healthy, and there was no lesion throughout the whole extent of the alimentary canal.

We are inclined to think that ptomaines formed in the sigmoid flexure and colon generally and were absorbed, producing at first their well-known toxic action of purging and finally paralysing the heat centres, and thus through hyperpyrexia producing death.

Unfortunately there was no discussion on the case, for the night it was brought forward had been fixed for the discussion of a different matter.

It is interesting to note that the general practitioner of the past dreaded any tendency to purging in children, and treated their little patients with a dose of castor oil, rhubarb, and a little solution of opium in the early stages of the disease.

His treatment was empirical, but it was empiricism based on years of observation.

## TROUBLE AHEAD IN PERSIA.

The St. Petersburg *Siedomosti*, which keeps a keen eye upon all matters in Persia, says that the Shah is very ill, and that he is not allowed to visit France this year (although his health was so greatly improved at the Contrexéville Springs during his last visit) owing to the jealousies of his vizier and his chamberlain. The Shah's previous trip to Europe was so expensive that there is no money to spare, and the Grand Vizier does not wish his master to go *incognito*, as he would then be under the influence of his enemy, the Chamberlain, and so his Majesty must suffer.

Prince Oukhtomsky's organ describes the heir to the throne, Mohammed-Ali-Mirza, as entirely uneducated, very ferocious, opposed to all reform, and a deadly enemy to all foreigners.

BERLIN, June 29th, 1901.

## TUBERCULOUS PERITONITIS.

In the *Zeitsch. f. Chir.*, 59, 3 and 4, Hr. J. Lauper, assistant in the Berne klinik, contributes a paper on

this subject. It consists of a report of twenty-two cases observed in Kocher's klinik. Fourteen of these were operated on, the remaining eight only having internal treatment. Sixteen of the patients were men, six women, and two children under fifteen years of age. Of the fourteen cases operated on, in most the peritonitis was of the serous form; in four it was purulent, and in three the dry adhesive form was met with. Operation mostly consisted in opening the abdomen; in three cases the tubes and ovaries were found and removed.

Of the fourteen cases operated on, ten recovered, equal to 70 per cent.; the other four died within a year, and whether tuberculous complication arose elsewhere was not known. No intestinal fissures were met with.

For the occurrence of recovery after opening the abdomen, the following factors were supposed to be responsible:—(1) Removal of the exudation, (2) improvement of the circulation and consequently resorption, (3) separation of adhesions, and (4) the removal where possible of the primary cause of the affection. Eight cases were not operated on from some cause or other, partly on account of complications in other parts. Four of these died and four recovered. In one case tapping seemed to have a favourable effect, and was recommended in all cases not suitable for further operation. Of the cases operated on and recovered seven of them had remained well for over four years.

In the *Zeitsch. f. Kl. Med.* Prof. Riegel discusses

## THE INFLUENCE OF MORPHIA ON GASTRIC SECRETION.

The experiments made were in agreement with those performed on animals, and were to the effect that morphia exercised no inhibitory influence on the gastric secretion, but that, on the contrary, its principal influence lay in exciting the secretion, even if the effect was not immediate. Only at first morphia appeared to check the secretion slightly, but the slight check was soon more than made up by a considerable increase. Whether the long continued use of morphine tended in the end to lessen the secretion, the writer's own experience did not allow him to decide. In his experiments on dogs, even when continued for several days, he never observed any diminution of the secretion. At the most the intensity of the stimulating effect in that direction was not so marked. The investigations make it clear that to give morphia in cases of ulcer of the stomach in the expectation that the acidity of the stomach will be diminished by it is a mistake. On the contrary, it appears desirable to bring into view and put into use the drugs that are known to have an inhibitory effect on the secretion. Whilst atropine and belladonna arrest the secretion in a marked manner, morphia increases it. Morphia may therefore be given in affections of the stomach only in cases where hyper-secretion will do no harm. When, however, excessive secretion is likely to be harmful, belladonna preparations are to be preferred, as in addition to the pain-relieving properties they also assist in checking secretion.

At the Congress for Surgery, Hr. J. Wolff, Berlin, read a paper on

## ARTHRALYSIS AND RESECTION OF THE ELBOW-JOINT.

In consequence of the unsatisfactory results of resection of the joint, the speaker had, in 1895, proposed arthrolysis for bony and firm fibrous ankylosis. He had performed the operation in nine cases. It consisted in cutting through or chiselling off, or in the removal

otherwise of all bony or fibrous structures that prevented free movement of the joint. In the case of an actress operated on in July of last year healing per primam was complete in eleven days. The passive movements then begun were, however, so painful, that the patient in the course of a few weeks declined to persevere. In September, therefore, a plaster dressing was applied, which was left flexible near the joint, and the arm was gradually brought to a condition of the utmost possible flexion and extension. From now active and passive movements were practicable. At present any difficulty or awkwardness of movement was scarcely noticeable, and the patient was able to follow her calling. When the disease in the joint was tuberculous, however, the ends of the joints so far as they were diseased had to be resected, and now the question arose whether the resection was to be typical or partial. Some operators preferred total resection in adults, but in children arthrotomy, so as to avoid arrest of growth. In a patient, *æt.* 31, typical resection was performed twenty-eight years ago, and when the arm was hanging loosely but little shortening appeared. Both humeri were of the same length. Ollier had observed an increased growth of the humerus after resection. The ulna also was highly developed. The case showed that even for children total resection might have its advantages over arthrotomy. The functions of the arm were good, flexion and extension were performed over a normal area and with normal power, and the patient was able for all her work.

In a case mentioned by v. Eiselsberg of a girl, *æt.* 17, with double ankylosis of the elbows, a good result was obtained in the left elbow, but bony ankylosis still continued in the right.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 29th, 1901.

### SUICIDAL EFFORTS.

At the meeting of the Prague Medical Association many interesting and important subjects were discussed and cases exhibited. Among the latter was a shoemaker, *æt.* 46, who had mutilated himself with a trimming knife 12 cm. long = 4.7 inches. There was one long cut across the mamma, a stab in the seventh left intercostal space passing through pleura and diaphragm causing pneumothorax; another cut 1.6 centimetres below ribs into the stomach at the fundus, the contents of stomach passing into peritoneum when admitted; and, lastly, a wide opening across the abdomen through which protruded four metres of intestine, omentum, and mesentery, covered beyond recognition with straw, pitch, dirt, &c.

The stomach was first stitched, the omentum resected, the bowel replaced, the whole abdomen washed out, and proper drainage provided for by gauze strips.

On the third day post-operation symptoms appeared in the form of circumscribed peritonitis. The abdomen was again opened and an abscess discharged; the abdomen was allowed to remain open for twenty days, when granulation became general. Six weeks later a

plastic operation was performed that healed in fourteen days.

### RECOVERY FROM INTUSSUSCEPTION.

Jedlicka demonstrated a case where intussusception assumed a peculiar form of recovery. On many occasions the patient had suffered from fits of constipation and obstruction of the bowel. In one of these attacks half a metre of the bowel came away, which gave relief. Four years later an abscess formed in the abdomen, which was opened, but owing to the subsequent stenosis laparotomy was performed, when the bowel was found to be invaginated. This had been perforated in a peculiar manner through the mesentery and not through the intussuscepted bowel as might be expected. One of the convolutions was greatly dilated and was resected. Inside the part removed was found a stercoral abscess.

### RARE FORM OF STRICTURE.

Jedlicka brought forward another female on whom he had operated for volvulus with supposed strangulation.

On the second occasion there was strangulation, with an adherent tumour on the appendix, which extended as a peritoneal band to the sigmoid flexure. In the third operation, which was within three weeks after the second on account of obstruction, a recent adhesive peritonitis had occurred. Recovery took place after jejunocolotomy was performed.

### CARDIAC TUBERCULOSIS.

Hlava showed a pathological preparation taken from a young man, *æt.* 35. The myocardium of the right auricle was greatly enlarged, while the cardia was filled with a mass of tuberculous nodules, with caseous masses in the walls and pericardium, while the lymphatic glands were greatly enlarged.

## The Operating Theatres.

### ST. THOMAS'S HOSPITAL.

**CHOLEDOCHOTOMY.**—Mr. BATTLE operated on a woman, *æt.* 35, who was suffering from painful attacks in the region of the gall-bladder. She had been under his care at the hospital two years before for a movable right kidney, and the operation for this condition had been very successful. It was principally undertaken for pain, and as she had obtained relief from that pain, she came to see if something could not be done for her present illness. For a month or two at intervals she had had severe attacks of pain, commencing in the liver region, so intense that she had been doubled up with them and vomited, whilst on one or two occasions she thought that there had been some "yellowness of the eyes" afterwards. Examination of the hepatic region showed nothing abnormal. She was kept in the hospital under observation for a fortnight, during which time she was permitted to get up and walk about, but no pain was complained of. At the end of this time she was so anxious to have something done that it was decided to explore, on the possibility of there being a gall-stone present to account for her symptoms. At the operation an incision was carried through the rectus muscle over the position of the gall-bladder, and this last was examined: it was small, about the size of the end of the thumb, and contained some inspissated bile near its fundus, but no definite calculus. Four inches from the surface, however,

a small stone could be felt, blocking the cystic duct, and it seemed probable that this was the cause of her symptoms, the gall-bladder and duct behind it being abnormally thickened. The lower aspect of the gall-bladder and duct was attached to the large intestine and omentum by a fold of peritoneum, possibly the result of some old inflammatory attack, and the stone could be felt with the finger on either side of this. The resident assistant-surgeon, Mr. Corner, held the stone between two forefingers and pressed it forwards and to the right so that it came within reasonable distance and could be removed. An incision was made over this, and it escaped through the opening thus made, a small quantity of bile which followed it being received on the gauze with which the area of operation was packed. The duct was steadied in the same position by Mr. Corner until it had been sutured, Lembert's sutures being inserted. The wall of the cystic duct was very hard, as well as thickened. Before the stone was cut down upon an attempt was made to move it towards the gall-bladder, but it could not be shifted. The calculus was about the size of a horse bean and rounded in shape; it presented no facets. The wound was closed fully, no drainage being employed. Mr. Battle remarked that it was evident this stone was the only one, and as its impaction in the cystic duct was quite capable of causing symptoms, it was fair to presume that the operation would fully effect its object. The attacks of which the patient complained were typical of gall-stone colic, but the position of the stone could not be exactly ascertained because the question as to jaundice was doubtfully answered. The cessation of the pain whilst in the hospital was, he thought, probably the result of the rest and regular dieting, therefore it was possible to make definite observation whilst she was waiting.

GREAT NORTHERN HOSPITAL.

SARCOMA OF OS CALCIS (*continuation of case on p. 612, June 5th, 1901.*)—Mr. PEYTON BEALE operated on the same man from whom he had previously removed a myeloid sarcoma occupying the whole of the interior of the os calcis. At the previous operation he was unable to do more than scoop out the growth. The latter recurred within three weeks, and having regard to the fact that it was limited entirely to, and had replaced the cancellous tissue in, the os calcis, and that it was a myeloid sarcoma, and therefore not likely to exceed its present limits, it was thought desirable to remove only the entire os calcis. A vertical incision was made over the heel extending upwards about three inches, and for the same distance along the sole; the attachment of the tendo-Achillis was divided and the periosteum with attached ligaments separated as far as possible from the bone; the posterior half of the os calcis was then removed and the calcaneo-astragaloid ligaments being next severed, the upper articular surface together with the cartilage, which was quite normal, was taken away; then the anterior surface articulating with the cuboid was separated from the latter bone by dividing and stripping off the calcaneo-cuboid ligaments. Thus the whole of the os calcis was removed. The cavity was then well washed out, the ragged ends of the ligaments were cut off, and the tendo-Achillis was sutured to the plantar fascia by means of strong catgut. The wound

was finally closed with the exception of about one inch below, and through this the large cavity was stuffed with cyanide gauze. Mr. Beale said that this operation appeared to him to be adequate, because the growth had not extended through the compact bone of the os calcis at any point, moreover the cartilaginous articular surfaces were perfectly normal. It had been said that in a case of myeloid sarcoma it was only necessary to remove the growth itself, that is the actual cancellous bone, and, in the case of a long bone, the contents of the medullary cavity, but Mr. Beale had seen many cases in which proceedings of this kind had been carried out even with the subsequent application of pure carbolic or strong chloride of zinc solution, and yet the growth had recurred; he believed, therefore, the right course to adopt in cases of myeloid sarcoma was to remove the whole of the bone in which the growth was in contact, after having carefully stripped off the periosteum, by this means further recurrence was always avoided; moreover it ensured the formation of more or less new bone to take the place of that which had been removed.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 3, 1901.

STATISTICAL FALLACIES IN REGARD TO LUNACY.

The statistics of insanity, though at first sight somewhat arid reading, are, in reality, replete with interest. From them can be extracted without much trouble a number of conclusions which throw an interesting if often fallacious light on the causation and incidence of mental disorder. Statistics are notoriously susceptible to skilled manipulation, and are even more apt to mislead when made use of by the unwary or hasty. Let us consider, for instance, the influence of celibacy as a cause, or shall we say, as a predisposing factor in the causation, of insanity. We find on looking through the Bethlem Hospital returns for last year that out of a grand total of 226 persons of both sexes suffering from some form of mental disease, 130 were single and only 83 married. These figures, taken alone, would

appear to justify the assumption that celibates are more prone to mental disturbance than the married, but, as we shall show, the difference in the incidence is more apparent than real. Taking the total number of admissions we find that they comprised 142 females and 84 males. Of these, there were ninety-four single women and only thirty-six single men, whereas, among the married, the proportions were forty-three males and only forty females. Of the patients who remained under treatment thirty-four married men almost balanced thirty-one married women. One obvious conclusion from these returns is that celibacy in the female is a more potent factor in the determination of insanity than it is among males. But is the comparison a just one? Celibacy in the female, we may take it, really implies approximate chastity, whereas in men we doubt if that can safely be advanced. The male celibate probably indulges his sexual appetite less frequently than his married brother, and presumably only goes astray at intervals, in deference to physiological stimulation. For the purpose of our argument we will assume that we are dealing only with persons who are predisposed by heredity or defective general health to some form of mental breakdown, and such subjects are, from this point of view, better off single than married, because in the latter state there is always the possibility of excessive sexual indulgence, plus the added sense of responsibility associated with the maintenance of a family. On the other hand, there are many reasons why the single state should weigh more heavily upon the unmarried female than upon the bachelor. The absence of physical and mental excitement, within healthy limits, in the life of the old maid, her naturally emotional temperament, exasperated by greater amenability to religious and other sources of psychical disturbance, render those already predisposed thereto exceptionally prone to disturbance of mental equilibrium. The influence of religious belief in respect of the incidence of insanity is another point which is of interest, though the statistics are subject to so many sources of fallacy as to be valueless from a scientific point of view; moreover, whatever the conclusion one may draw from the figures, it is always open to the critic to object that the religious factor was the result, and not in any sense the cause, of the breakdown. Of the 226 patients already referred to, 155 were registered as members of the Church of England as against thirteen Baptists and Roman Catholics respectively. We need not insist upon the inconclusiveness of any deduction establishing a special proneness to insanity among the members of a particular church. Nor are the returns of the "cured" more trustworthy from a statistical point of view. Of the 155 members of the Church of England only sixty-two were discharged during the year as "cured," and of eight Wesleyans none recovered their mental equilibrium. There do not seem to have been any agnostics or freethinkers, unless we accept the entry of *nil* in two instances as evidence of an absence of religious belief.

#### SYPHILIS AND GENERAL PARALYSIS.

THE etiology of general paralysis remains obscure in spite of the great advances that have characterised recent scientific knowledge of diseases of the nervous system. The malady has been recognised only within the limits of the last hundred years, and so far as can be gathered from the experience of experts it has of late increased rapidly in incidence. Possibly, however, that conclusion may be to some extent attributable to improved diagnosis, but after making allowance for a margin of error in that direction, there is no doubt that a greater proportion of patients suffering from general paralysis are now admitted into lunatic asylums, and that the tendency has been for the disease to develop at an earlier age-period, so as even to include childhood. From whatever point of view we regard the condition, its progressive nature in spite of treatment renders its study one of the most important within the range of modern medicine. For that matter general paralysis may be ranked with cancer and mycosis fungoides as members of the happily diminishing group of the incurable and deadly ills that affect mankind. We know that it is definitely connected with certain predisposing conditions, such as a neurotic family history, injuries to the head, dissipation, mental worry, alcoholism, sexual indulgence, and other exhausting influences, but above all, syphilis. The conviction of the importance of syphilis as a causative factor in general paralysis has grown stronger and stronger, although it must be admitted that there are still missing links in the chain of complete proof. Statistics on the subject must necessarily be received with caution, for as every medical man knows, it is often extremely difficult to get a history of syphilis, direct or indirect, in many undoubtedly syphilitic manifestations. However, it may be broadly stated that the brunt of general paralysis falls upon men rather than women, upon soldiers rather than upon priests and women of the better classes and upon the population of cities rather than of the country. In other words, the malady is found most prevalent where there is the greatest amount of syphilis. The method of the action of the syphilitic taint upon the brain is unknown, although it is possibly or probably to a great extent due to vascular affections leading to chronic inflammation and disturbance of nutrition. A similar want of precise knowledge must be pleaded with regard to locomotor ataxy, in which syphilis is now generally regarded as a common if not exclusive cause. In both diseases of the nervous system there must be some localising conditions, inasmuch as many persons suffer from syphilis whereas comparatively few develop either general paralysis or locomotor ataxy. In this way we are once again faced with the wisdom of the homely proverb which teaches us that prevention is better than cure. Do away with syphilis and you do away with the two disastrous and incurable nerve maladies in question. So far as syphilis is concerned a good deal of advance has been

made in the scientific treatment of the disease, but a great deal remains to be done by way of social reform. The Contagious Diseases Act was undoubtedly a step in the right direction. The scientific sanitarian may confidently look forward to the time when syphilis will not be sown broadcast among our population in obedience to the prudery and prejudices of a set of worthy but misguided sentimentalists.

#### ABDOMINAL PAIN IN TYPHOID FEVER.

THE significance of pain in typhoid is known to all clinicians. But the difficulty of defining the thing signified by the pain has been so appreciated by writers that practically no attempt has been made by writers on typhoid fever to attempt a differentiation of its many varieties and meanings. Louis' "*Recherches sur la maladie connue sous le nom de gastro-enterite*," found it difficult to distinguish between pain in typhoid that told of impending death and simple flatus. Jenner was not more successful, and even the classic work of Murchison and the great monograph of Liebermeister make no attempt to guide the student in the interpretation of this frequent symptom of this very common disease. Within the past few weeks it has been seriously proposed to open the abdomen, and if necessary the intestines, and seek the cause. Indeed, as a writer has proposed, in cases of pronounced meteorism an incision into the head of the colon and washing it out would be a perfectly justifiable operation. Tympanites cannot, however, account for more than a small percentage of cases in which pain is a marked symptom, and even with the aid of the surgeon, the cause will remain unknown in many cases. This is in part, at all events, due to the fact that the alimentary canal is so richly supplied by the sympathetic nervous system, of the physiology of which there is still much to be learned. The whole question has been very ably dealt with by Dr. Thomas McCrae (*New York Med. Jour.*) who urges that "It is not necessary to establish the importance of an accurate knowledge of this system." As the author says, the question of the cause of pain may arise quite suddenly, and may be associated with other symptoms of a deceptive character, which so mask the symptom of pain that a perforation may be undetected and a life lost that prompt surgical interference might have saved. From the record of some five hundred cases of typhoid in the Johns Hopkins Hospital, he found that pain occurred during the course of the attack in 32 per cent. of the cases; of these the pain was due in some cases to conditions apart from any special lesion of the disease: hysteria, lung conditions, bladder, abortion, labour, and menstruation. In another group of cases the pain was due to conditions of the gastro-intestinal tract apart from complications: vomiting, constipation, diarrhoea. Besides these the symptoms were found in abdominal conditions apart from specific bowel lesions: appendicitis,

peritonitis, cholecystitis, liver abscess, painful spleen, phlebitis. The specific intestinal complications associated with pain were hæmorrhage and perforation. And in other cases no discoverable cause was found. The physician is fortunate when hæmorrhage and perforation give rise to pain, and when his patient possesses sufficient consciousness to tell of its presence. Of thirteen cases of perforation the author found the lesion to be attended with a definite sudden onset of pain in two of them; but in three cases the pain was complained of some days before the perforation. Considering the gravity of the symptom all nurses should be instructed to immediately summon the medical attendant in all cases of abdominal pain. And we think that in serious cases of typhoid opiate, as likely to mask pain, are to be avoided.

#### Notes on Current Topics.

##### The Reorganisation of the Army Medical Service.

A "COMMITTEE of experts" has been nominated for the purpose of considering a scheme which Mr. Brodrick has drawn up for the future organisation of the Army Medical Service. This committee comprises the names of Mr. Howard H. Tooth, M.D., F.R.C.P., St. Bartholomew's Hospital; Mr. George H. Makins, F.R.C.S., St. Thomas's Hospital; Mr. Alfred D. Fripp, C.B., F.R.C.S., Guy's Hospital; Sir F. Treves, K.C.V.O., C.B., F.R.C.S., London Hospital; Mr. Alexander Ogston, M.D., Scotland; Lieutenant-Colonel Keogh, M.D., C.B., R.A.M.C., Ireland; Mr. E. C. Perry, M.D., F.R.C.P., Senate of London University; Surgeon-General Hooper, C.S.I., President of the Medical Board, India Office; and two officers who will be named by the Commander-in-Chief to represent the Army. The secretary will be Major H. E. R. James, R.A.M.C., and the chair will be taken by Mr. Brodrick himself. These names convey an assurance that the purely medical aspect of the service will receive due attention, though until we are in possession of the actual terms and scope of the reference it is impossible to gauge the precise significance of this important step. Some objection has been taken to the inclusion of Sir Frederick Treves, but we hold, on the contrary, that his experience will be of the greatest value, for he is as alive as anyone to the requirements of the service. It is doubtful whether the committee will be enabled to report before the end of the present session of Parliament, but, as Mr. Brodrick aptly observed, it is much more important that they should come to a correct conclusion than that they should be hurried in the performance of the duty assigned to them. On the other hand, the subject is one which has been exhaustively discussed for many years past, and the general lines on which reform will have to be carried out are pretty well agreed upon—a higher status, more liberal remuneration, and more considerate treatment at the hands of those in power. It need certainly not take long for the committee to formulate

its conclusions, but it may take Mr. Brodrick some time to bring these conclusions to a practical issue. We are justified in hoping that this great question will now be dealt with on a statesmanlike basis, and that the future Army Medical Service will be placed on a footing worthy alike of its members and of the interests confided to their charge.

#### The Treatment of Paralysis Agitans.

IN a former number we noted an additional method of diagnosing the onset of paralysis agitans, and now it is of interest to find a contribution on the symptoms and treatment of this disease by Dr. R. L. Williamson in a recent copy of the *Manchester Medical Chronicle*. Recognising that in the light of our present knowledge there is no treatment which can cure or even permanently arrest the progress of the disease, he has devoted a considerable portion of his article to a consideration of certain measures he has tried for the relief of the more troublesome symptoms. He strongly recommends that a patient should remain in the open air as much as possible, and has found that driving in an open carriage, in some cases, produces a temporary cessation of the tremor. He has tried a large number of drugs, but has found all of them practically useless with the exception of hyoscine, hydrobromate, duboisine sulphate, and hyoscyamine which he believes are of decided value. In using the first of these drugs he suggests that the initial dose should not exceed  $\frac{1}{150}$  gr. dissolved in 3ij of chloroform water. The quantity may be increased gradually up to  $\frac{1}{100}$  gr., and in some cases, when no toxic symptoms have appeared, he has given as much as  $\frac{1}{75}$  gr. or  $\frac{1}{5}$  gr. by the mouth. Dr. Williamson always uses Merck's hyoscine hydrobromate, obtained directly from Darmstadt. If hyoscine fails to relieve the tremor he suggests a trial of duboisine sulphate ( $\frac{1}{4}$  gr. by the mouth) or by hyoxyamine sulphate ( $\frac{1}{8}$  gr.), but as a rule these are not so efficacious as hyoscine hydrobromate.

#### Dysbasia Intermittens Angiosclerotica.

THESE are not wanting in literature instances of persons, generally past middle life, who complain of being unable to walk more than a short distance by reason of what they describe as "cramp in the legs." That remarkable clinical observer, Charcot, thought that the condition was practically one of sclerosis of the arteries of the lower extremities, and the condition appears to be associated with vascular spasm. The usual history in these cases is that after a short period of repose the sufferer is able to resume his promenade. Putnam (*Boston Medical and Surgical Journal*, February 21st, 1901) has just published the details of an extremely interesting example of this affection, called by some intermittent claudication, and sometimes referred to as intermittent lameness. The name which Putnam applies to this symptom-complex, "dysbasia intermittens angiosclerotica," though somewhat unwieldy for general use, certainly indicates very

accurately the peculiar difficulty experienced in walking, the intermittent character of the attack, and the pathological relation of the disorder. In this curious malady it has been found that the therapeutic use of electricity and baths has not been followed by any beneficial effect, and in the case quoted it is worthy of note that upon the patient, of his own initiative, taking to kneading his calves every night and morning marked improvement followed.

#### Quinine Idiosyncrasy.

IDIOSYNCRASIES have long been known and recognised. Montaigne refers to them, as do Aaiatus, Lusitanus, and Spigelius, and many other authors, but they one and all looked on them as curiosities of medical experience until M. Lorry published his "Tractatus de Morbis Cutanée" in 1777. The great importance of recognising rashes due to idiosyncrasies came in time to be recognised, and under the title "Antipathies" Milligan and other writers collected numerous examples. But until Prince A. Morrow's great monograph, "Drug Eruptions," few medical men had any idea that drug rashes so closely simulated the exanthemata. Among the more generally used drugs Dr. Morrow gives a formidable list of the eruptions that follow from the use of quinine, from the well-known pamphlet of Jean Baptiste Chevallier (1835) up to 1877. He has shown that in the majority of cases the rashes assumed a scarlatinoid, or, as more modern writers might say, "a fourth exanthem" form, "followed by desquamation of a branny or lamellar character," and of course liable to be mistaken for scarlatina, particularly as the tonsils are not infrequently inflamed, and the temperature rises to 102° F., and in some cases was as high as 104° F. or even 105° F. Of recent cases the most interesting are those given by Dr. H. A. Hare (*Therapeutic Gazette*):—"A man fifty-three years of age, was ordered a pill containing about one-sixtieth of a grain of arsenious acid and two grains of quinine three times a day as a tonic during convalescence from a severe illness. Within twelve hours of the administration of the first pill he developed an intense erythematous rash all over his body, with intense itching and puffiness of the skin about the face. At the end of five days with the subsidence of the acute injection of the skin, marked desquamation took place over all portions of the body with the same freedom as is frequently seen in severe scarlet fever, and six weeks afterwards the skin on the palms of his hands and the soles of his feet was still actively desquamating. No sooner had the symptoms appeared than the patient asked if he were receiving quinine, and on being told that he was getting the drug, he immediately recognised the cause of his difficulty, stating that he always had a similar affection when this drug was administered, even when it was given in remarkably small quantities." For this patient's daughter, a woman of twenty years of age, Dr. Hare prescribed a pill of iron, arsenic, and quinine, and she, too, developed "a general rose

rash all over her body," which was followed by an active desquamation of the palms of the hands and soles of the feet. Where a quinine idiosyncrasy exists even the topical application of the alkaloid will produce an eruption. Delieux de Savignac reports a case in which the application of a pomade containing quinine produced intense pruritus and an eruption of lichen. As quinine has now practically become a domestic remedy, it is well in all suspicious cases to inquire if the patient with an ill-defined rash has been taking the drug.

#### Sponges in Abdominal Wounds.

In the case of a surgeon who was sued for malpractice, because the head-nurse of a hospital who was personally in charge of the sponges at an abdominal operation forgot that one had not been removed before the wound was closed, a verdict was given acquitting the surgeon of blame, but the matter has aroused further interest because it is now sought to prove that the hospital employing the nurse is responsible. He would be a rash man who counted upon the Law Courts acquitting a surgeon who was aware that a nurse assisting at an operation was in any way careless, but it certainly would be manifestly unfair to hold an operator responsible for the acts of a duly qualified nurse on the ground that she was technically the surgeon's agent. A new terror will be added to the life of a hospital surgeon if he is to be held accountable for whatever may happen to his patients in consequence of the shortcomings of the nurses on whom he must depend in his work.

#### Cabmen and Street Accidents.

A FEW days ago a well-known actress found lying in the street a child who had been crushed by a grating. She hailed a cabman, whose first question was not unnaturally who was to pay him his fare for taking the child to a hospital. The point being settled, the little sufferer was removed to the desired haven of safety after a delay of four or five minutes due to the discussion about payment. In a subsequent interview published by a London newspaper the lady in question raised the point as to the duties of cabmen in case of accidents. Clearly enough there is no law that can compel the driver of a cab to carry persons gratuitously, no matter what their physical extremity may be. That fact occasionally leads to exhibitions of callousness in the streets of London that would be worthy of Chinese cruelty in its most cynical form. A man may be picked up writhing and half dead after being run over by an omnibus or other vehicle, and the first question asked him by the bystanders is probably whether he has any money to pay for a cab. The police are empowered to carry off in a cab any person who is ill or has met with an accident in the streets. The hospitals certainly do not pay for cabs that bring patients to their doors. From the point of view of the cabman, there is much to be said against his being made the vehicle of compulsory charity. As

a rule he has hard work to make both ends meet, and his employer would make no allowance for time spent in carrying disabled persons from one place to another. Again, the cabman is answerable for any damage done to his cab, and he would be liable to any amount of mischief from persons picked up in the street. Some years ago when a woman jumped from the suspension bridge at Clifton and fell in the mud a cabman passing by refused to take her to the hospital because of the damage the mud with which the unfortunate woman was covered would do to his cushions. The best plan would be for the hospitals to pay fares in all clearly suitable cases. The public would certainly not grudge the money spent for so necessary a purpose.

#### The Leper Mission.

It would be not easy to imagine any mission framed upon a more absolutely ideal Christian basis than that which has been organised to the lepers of India. It is to be feared that the extent to which that loathsome disease prevails in our great Eastern dependency is not generally recognised by the dominant nation here at home. In 1898 the Indian Government passed an Act providing for the segregation of mendicant lepers, and forbidding lepers to handle food or to carry on trades dangerous to the community. It has recently been resolved to enforce that measure in Bengal, presumably as an experiment to test the feeling of the native population. In Nepal it has been stated that a person found to be suffering from leprosy is sometimes buried alive by the Brahmins, and in Sumatra at times the relatives of a leper burn him to death in his house, pushing him back into the flames should he attempt to escape. The mission does not confine its energies to India, but does good work also in China and Japan. It has no less than sixteen centres of work, and supports twenty-seven asylums or settlements, and in this way does its best to care for about a million lepers said to exist in the countries above mentioned. In India the housing and food of an adult leper can be provided at the modest rate of £5 a year. As a preventible disease leprosy can be banished from the face of the earth by the strenuous application of modern preventive science. Unhappily, it seems likely to linger for generations in India, which under present conditions is the favoured home of cholera, enteric fever, plague, and other specific scourges of mankind.

#### Beauty Making.

THE desire for beauty on the part of the female is one of the most deeply-rooted characteristics of the human race. That it is answerable for a vast amount of folly and frippery goes without saying. Unfortunately the door is thrown open thereby for the host of harpies who batten upon the foibles and weaknesses of mankind. In this way abound myriad specialists in baldness, in the destruction of superfluous hair, in the removal of fat, wrinkles, freckles, moles and blemishes of all and sundry

kinds. To a certain extent the treatment of many facial defects, such as an everted eyelid or a disfiguring birthmark or scar falls within the limits of legitimate surgery. But the value of such procedures is ascertainable upon a moderate and well-defined basis. The claims of the quack, on the other hand, are boundless, and would be ridiculous to any but a woman whose judgment was swamped by an overwhelming desire for sexual attractiveness. A New York lady, so it is announced in the *Daily Express*, has brought an action for £12,000 damages against some operators who undertook to restore the youthful contour of her face, to make a dimple in her chin, to raise the drooping eyelids, to draw back the skin and make it smooth on the forehead, to redden her lips, and straighten and point her nose. It will not surprise any practical surgeon to learn that a series of operations to fulfil that extremely large order resulted in making the lady plainer than ever, with the addition of numerous scars. It is to be hoped that the publication of this distressing case will stay, for a time, at any rate, the hand of the professional beauty maker.

#### Instruction in the Use of Anæsthetics.

THERE are rumours that instruction in the administration of anæsthetics is soon to be included in the curriculum, and one's feeling must be that of mild surprise that this important detail should hitherto have escaped adequate treatment. The difficulty in the way of ascertaining the practical knowledge of the candidate in this direction does not account for the fact that no questions are usually set on the subject. We do not hesitate to affirm that a certain proportion of the deaths from anæsthetic narcosis which it is our melancholy duty to chronicle from week to week are more or less attributable to the fact that practitioners have, for the most part, to learn to give chloroform as best they can in actual practice. The basis of such teaching will of course be an intimate knowledge of the physiological effects of anæsthetics in large and small doses, but the various methods of administration must also be taught, and every candidate should be required to show that he is familiar with the use of some kind of regulating apparatus. The reluctance of most practitioners to employ any apparatus is, we believe, largely the result of their ignorance of its use, yet in this direction, in all probability, lies the secret of safety in anæsthesia. No apparatus yet devised can avert risk in the hands of the careless and inexperienced, just as no measure, however accurately graduated, is of itself an obstacle to a poisonous dose of a drug being dispensed. On the other hand, death under chloroform when such an apparatus is resorted to, is the rarest of occurrences and almost without exception those which it falls to our lot to record, have followed the old-fashioned practice of pouring the drug on to a towel or mask. Apart from the risk of inducing fatal narcosis, imperfect anæsthesia militates against the success of

the surgeon, who is seriously handicapped when, in addition to the problems requiring his immediate attention, he is hampered by difficulties of this kind. No doubt when the subject comes up for consideration before the General Medical Council a sufficiently comprehensive schedule will be devised, and a notable lapsus in medical training will thus be remedied.

#### Trichinosis.

A CERTAIN Professor Joseph Leidy, about fifty years ago, in cutting a slice of cold ham to make a sandwich, noticed a number of little specks, and, as the *Journal of the American Medical Association* puts it, the fact that Leidy's scientific curiosity got the better of his appetite gave rise to a special occupation which now gives employment to over 50,000 persons, which resulted in the prohibition of American pork into Germany for a period of nine years, entailed on American exporters a financial loss estimated at millions of dollars, saved hundreds of human beings from disease and death, inaugurated an elaborate system of public hygiene, and gave a mighty impulse to the study of the etiology of disease. It is a curious fact that during the exclusion of American pork from Germany there was an annual average in that country of 454 cases of trichinosis, but since the re-admission of American pork in 1892 the annual average has only been 149. In the opinion of so great an authority as C. W. Stiles, the total prohibition of German pork in Germany and the compulsory use of American pork would probably do more to eradicate trichinosis than does their elaborate system of microscopic examination. In Germany there is a widespread custom of eating raw pork, and a feeling of false security is fostered by reason of the Government employing an enormous number of trained observers to microscopically inspect the commodity. It would be wiser to educate the consumers so that they would of themselves abstain from partaking of pork that was not thoroughly cooked or cured. Outbreaks of the disease in this country have brought the subject of trichinosis into prominence, and the recent address of C. W. Stiles before the Philadelphia Pathological Society, published in Volume IV. of their "Proceedings," should receive the very closest attention of all who are interested in the public welfare.

#### Gold Blindness.

HYPERMETROPIC members of the dental profession who are also astigmatic are in some cases liable to lose the power of distinguishing gold-filling from the tooth on which they are working. This form of retinal asthenopia appears to be due to abnormally rapid exhaustion of the visual power, and the trouble is noticed to occur when the eyes have been kept fixed upon a small gold stopping for a length of time, the warm yellow colour of the metal tending to exaggerate the preexisting defect. In addition to inability to distinguish the filling from the tooth dentists who present this defect cannot recognise

clearly the contour of the hole they are stopping. In the *Canadian Practitioner* for June it is pointed out that age does not predispose to this affection nor does youth exclude it. The primary cause of this particular form of blindness indeed is probably the excess of yellow rays from the gold metal. After a few days' rest the sufferer is enabled to resume work as before, but recurrence frequently takes place, and the intervals during which work can be carried on become shorter and shorter. The treatment suggested by Mr. L. Webster Fox is, first to correct any error of refraction, to examine carefully into the general health of the patient, and to advise that nothing tight be worn round the neck. The last direction is necessary in consequence of so much dental work having to be done with the head bent. The intense white light which accompanies the fusing of gold plates contains an excess of yellow rays, and it is suggested that this constitutes the causative factor in the disorder.

#### A Difference of Opinion.

THE best way, when there is a difference of opinion between practitioners in regard to a case, is for them to have a fresh examination when both are present. It can be but seldom under such circumstances that they will fail to arrive at a common accord. Unfortunately, this course is not always practicable, nor is it usually resorted to even when it is. A regrettable difference of opinion became manifest at the Westminster Police Court last week in reference to the mental condition of a refractory young woman. The medical officer of the prison and the divisional surgeon both arrived at the conclusion that she was insane, and she was sent to the workhouse infirmary. There the medical officer decided that she was sane and discharged her, thus placing the magistrate in a somewhat difficult position. True, this difference of opinion testifies to the conscientiousness with which the various medical officers fulfil their responsible functions, but it interposes grave difficulties in the administration of the law, and means ought to be found of settling such questions without throwing the onus of deciding the sanity or otherwise of the accused on the magistrate, who is hardly fitted to decide which view is the correct one.

#### Lady Medical Officers.

THE question of appointing a woman to the post of resident medical officer at the infirmary gave rise to an animated discussion last week by the Birkenhead Guardians. The Board had on a previous occasion declared by a large majority that they preferred a resident medical officer of the male sex, and had advertised *de novo* for one, but, as they only offer £130 per annum, not a single application was received in response thereto. Thereupon the Board resolved to appoint Dr. Eva McCall, at present Assistant Medical Officer at the Salford Union Infirmary, at a salary of £120 for a trial period of twelve months. We hope, without being over sanguine, that this lady will decline the

reduced scale of remuneration, because nothing is more calculated to maintain the hostility of the profession to female competitors than the willingness with which they, or some of them, play into the hands of parsimonious boards. We note that the lady's male colleague will be expected to take all the "objectionable" cases off her hands, but no mention is made of any arrangement which will rid this gentleman of cases which he himself may find objectionable. If ladies elect to compete in the medical field it must be in accordance with the principle of a "fair field and no favour."

#### Did Napoleon Die of Cancer?

THE belief is very general that the cause of death of the great Napoleon was cancer, and it is generally believed that cancer was in the family. Dr. Baudouin has lately published in the *Gazette Médicale de Paris* some clinical remarks on the death of Napoleon I., and the conclusion he arrives at, apparently on perfectly reasonable grounds, is that the great Emperor suffered from an ulcer of the stomach, which caused death by perforation. Undoubtedly hæmatemesis was present as a symptom, and at the autopsy there was no hypertrophy of the liver nor any signs of cancer, but a gastric ulcer which had perforated was found near the pylorus. The whole controversy exemplifies very clearly the extreme difficulty of correcting a 'mistake of this kind. It will be remembered that Napoleon's last illness was of about four years' duration, and this time would fit in with the diagnosis of cancer, though it is undoubtedly true that a competent authority diagnosed chronic hepatic disease and later abscess of the liver; but Dr. Baudouin believes this to have been a peri-hepatitis due to extension from the existing ulcer of the stomach.

#### The Cultivation of the Dragon-Fly.

ACCORDING to the reports of an experimenter, the time occupied by one dragon-fly in consuming 800 mosquitoes extends over sixty minutes. It is not stated for what length of time this useful fly can continue its process of destruction, but we learn that the proposal has been mooted to breed dragon-flies on an extensive scale with a view to finding out if their numbers cannot be so increased as to justify the hope that the mosquitoes, which play such an important role in the propagation of certain diseases, may be sensibly decreased.

#### Political Control of Hospitals.

THE superintendent of one of the most important hospitals in New York has suspended nearly 200 attendants, from March 1st up to May 1st, for intoxication. The male and female attendants apparently celebrate the advent of their pay-day by indulging unduly in alcoholic beverages. It is certainly an intolerable injustice that the political system of New York should be responsible for the appointment of drunken and disorderly attendants to an institution where their vicious behaviour inflicts on the suffering sick the additional misery of being compelled by their misfortunes to remain in an abode that must

appear at times to be, in more senses than one, a perfect Bedlam. A writer in the *Post-Graduate*, for this month, very properly says that if ward nurses are appointed because they belong to a political organisation, and can be relied upon to vote the "straight ticket," then a fitting motto to be placed over the wards would be "All hope abandon ye who enter here."

#### Acute Cardiac Failure.

THE subject which Sir Richard Douglas Powell chose for the subject of his Cavendish Lecture, which we publish elsewhere, is one of very present interest. There is a general impression that heart disease is more prevalent now than formerly, but this may be due to the close study which has been made of cardiac lesions, especially those which supervene suddenly and determine acute and even fatal symptoms. Our readers will find in this lecture many useful suggestions in regard to the prevention and treatment of this disastrous category of lesion. The public have still to be educated to the understanding that athletic pursuits, this frequent cause of cardiac breakdown, cannot safely be indulged in to an unlimited extent by every lad indifferently, and ought always to be conducted under some sort of medical supervision. There is often no warning of the mischief that is being wrought, and its extent often only becomes appreciated when the harm has been done, hence the necessity for practitioners to use their influence to avert impending disaster. The conditions under which injury to the heart may result in the young differ in many important respects from those which menace subjects more advanced in years. For instance, the young are more apt to suffer from the effects of prolonged strain, while the elderly are more exposed to risk in connection with sudden strain even of short duration. In these days of cycling, touring, and other forms of family holiday exercise, this difference is one to bear in mind, and it would be a good thing if the lecture in question could be divested of its technicalities, and popularised so as to admit of its being read and understood by the public.

#### The Viavi Fraud!

NOTWITHSTANDING recent convictions, the agents of this abomination appear as active as before; after exploiting England and Ireland, Scotland is now *en tour*, and a few days ago advertisements appeared in the Glasgow newspapers with reference to lectures to ladies which were to be delivered in the city. At one of these lectures we are informed that about thirty ladies were present, and they were treated to afternoon tea. The lecture was delivered by a female who spoke of the Viavi remedies (?) as "food for the ovaries." She fully explained the menstrual function, and went into detail with regard to the various disturbances in connection with it. In such cases the capsules and ointment required cost £3 10s.! Recently an action against the Viavi Company by a lady who had been induced to undergo the treatment resulted in a verdict with £50 damages and costs on the

higher scale. The Judge, in commenting strongly on the case, said "it was the most important that had ever come before him." In another case, where an inquest was held on the body of a child aged seven years and 10 months, a box of ointment had been used which cost £1 16s. It would seem that this Company, which has already acquired considerable unenviable notoriety, pays their agents 50 per cent. on the sales effected. Perhaps it should be mentioned that the person representing this Company in Glasgow, which remunerates their agents so generously, has been recently engaged in the laudable work of promoting and assisting with other charitably disposed Glasgow folk in supplying the poor in courts and alleys with soul-inspiring music.

THE death is announced of Mr. James Stalker, M.R.C.S., L.R.C.P., formerly of Liverpool, who succumbed to fever contracted in the discharge of his duties as medical officer of the Colonial Medical Service on the West Coast of Africa.

THE Secretary of the Royal College of Surgeons of England announces that the additions made to the Museum during the past year will be exhibited in the Council Room on Thursday, Friday, and Saturday, July 4th, 5th, and 6th. Fellows and Members are invited to attend.

#### PERSONAL.

SURGEON-COLONEL SAUNDERS, Royal Army Medical Officer at York, has been appointed Administrative Medical Officer of the Madras Presidency.

DR. ISAMBAARD OWEN has been offered the post of Principal of the University College of South Wales, left vacant by the death of the late Professor J. V. Jones.

THE EARL OF ROSEBURY will take the chair at the twenty-eighth festival dinner of the Royal Medical Benevolent College on Tuesday, July 9th, at the Hotel Cecil.

THE professional jubilee of Dr. A. R. Mackenzie, of Fortrose, N.B., was celebrated at Rosemarkie last week, when a large number of medical men assembled to do honour to the occasion.

DR. F. W. HEWITT has been appointed Emeritus Lecturer on Anæsthetics at the London Hospital, on his resigning the post of Instructor in Anæsthetics which he has held for fifteen years.

THE baronetcy conferred on Dr. William Selby Church, President of the Royal College of Physicians of London, which has already been announced in these columns, was officially gazetted on Friday last.

WE understand that Mr. Hy. S. Wellcome, principal of the firm of Burroughs Wellcome and Co., has offered to present the Gordon Memorial College at Khartoum with a bacteriological and analytical laboratory.

DR. HORSBURGH, Medical Officer of Health for Musselburgh, N.B., was the victim of a violent assault a few days since at the hands of three miners, who have since been fined £1 each. Such a mild sentence is well calculated to *encourager les autres*.

THE HON. ELLA CAMPBELL SCARLETT, M.D., daughter of Lady Abinger, sailed last week in the transport "Assaye" for South Africa, having been appointed by the Colonial Office one of the doctors to the Refugee Camp in the Orange River Colony.

THE HON. MRS. TALBOT, who was specially deputed by H.B.H. Princess Christian to perform the task, formally opened the St. John's Hospital, Morden Hill, Lewisham, on the 24th ult., with the support of the Bishop of Southwark.

DR. EVA M'CALL, Assistant Medical Officer to the Salford Union Infirmary, has been appointed Assistant Resident Medical Officer to the Birkenhead Union Infirmary. There was opposition to the appointment of a lady doctor, but an advertisement offering a somewhat higher salary brought no application from the male element.

THE important post of Medical Superintendent of the Banstead Asylum, Surrey, is about to become vacant. Attached to it is a salary of £1,000 per annum, with house rent and taxes free, and other privileges. The appointment is under the control of the Asylum Committee, London County Council, particulars of which will be found in our advertising columns.

### Galway.

[FROM OUR OWN CORRESPONDENT.]

#### THE LATE DR. KEAN AND FEVER IN ARRAN.

THE neglect to provide a doctor for Arran when the late Dr. Kean was lying ill from fever contracted in the discharge of his duty was brought before the Galway Board of Guardians by a letter from the Local Government Board in response to complaints made by the Rev. M. Farragher, the energetic parish priest of the island, who alone seems to have been alive to the seriousness of the emergency, and the inhumanity of leaving the sick doctor and islanders for a week without medical aid.

Who is to blame? In defence of the guardians it is stated "in justice to the guardians and to every member we did everything we could do to meet the circumstances though often at great trouble, and, for all that, have got this anonymous writer. A special meeting was called for the occasion, and two hours after we got the summons we met." Remarkable celerity, the guardians met in two hours, and seem to think that they deserve special credit for only this and nothing more; yet as the outcome of this "great trouble" and special activity, the islanders are left for a week without medical aid. Admitting that all the board of guardians could do at the time was to authorise the employment of a doctor, surely their duty does not end there, and they cannot disclaim responsibility. It was their business to see that their orders were obeyed.

Then there is the future to be considered; it is reported that fever still exists in the islands; it is possible that again there may be a sick doctor, and the guardians being content to say "We did all we could, we met at two hours' notice," it is probable that the doctor and islanders will again be left without medical aid. Blame attaches itself to the guardians for not holding a searching inquiry as to how it happened that no doctor was provided; but that apparently is just what they will not do. As their champion at the Board remarked, they "don't want to twist the matter and bring" anyone into it. This attitude is a distinct encouragement to a repetition of the "uncertain state of affairs," as the episode has been euphemistically termed, and the guardians do not seem to appreciate the gravity of leaving a fever-stricken community completely cut off from medical aid, except that rendered by the dispensary medical officer without a doctor.

All honour is due to the Rev. Wm. Farragher for his energetic and courageous action, but his efforts to prevent future mischief must be unavailing unless the guardians, or in their default the Local Government Board, show that even poor islanders cannot be neglected with impunity.

### Special Article.

#### DISCOVERY OF THE BACILLUS OF SYPHILIS.

A COMMUNICATION of the greatest importance was read by Drs. Justin de Lisle and Louis Jullien before the French Academy of Medicine yesterday (Tuesday), giving the result of their researches bearing on the specific bacillus of syphilis. This they claim to have discovered, and if their observations are confirmed the discovery may fairly be described as one of supreme importance.

These observers remark that although the blood of syphilitics has been found sterile by most previous investigators, it is on this fluid nevertheless that they carried on their observations, because they felt convinced that a constitutional disease like syphilis must necessarily infect all parts of the organism. They chose for their investigations cases of recently acquired syphilis in which no specific treatment had been resorted to. The blood experimented with was withdrawn direct from a vein under the strictest antiseptic precautions, and both the blood and the serum were then examined under the microscope. They found therein a rounded, granular, highly-refractile body, capable of traversing a Chamberland filter, possessed of marked mobility, of a kind already noticed by other observers. These bodies, however, never gave any result either in cultivation or by inoculation, a result which, they point out, should not excite surprise, in view of the recognised fact that the coagulated blood of syphilitics is incapable of conveying infection. This destruction of infective power is probably due to the presence in coagulated blood of a strongly anti-bacterial substance, alexine. In order to obviate the production of this substance they made use of blood plasma for their investigations, as well as of blister exudation, produced either in the ordinary way by means of cantharides, or by means of Mayor's hammer. In the plasma they found on several occasions a form of bacillus presenting the following characteristics: It is polymorphous, varying in shape from a short bacillus measuring from 5 to 8 m. in length, and from 15-100 to 3-100 of m. in width, to that of a long thread with somewhat rounded ends, not swollen into sledge-hammer shape. This organism is very mobile and moves freely in the field of the microscope. It takes all the usual stains, but it must not be dried in the flame or at a temperature above 60° C. The best stains are alcohol-ether, a solution of osmic acid, or a saturated aqueous solution of corrosive sublimate, acidulated by the addition of acetic acid. It does not take the Gram stain.

Bouillon inoculated therewith becomes turbid in twenty-four hours, and in the course of four or five days a slight cloud forms which does not spread or become thicker. Gelatine is slowly liquefied. When stabbed into gelatine it gives rise neither to the cone nor the extinguisher, the liquid in the tube is flaky, and of a greenish hue. The gelatine is not coloured and its surface remains even. On gelatine *ex botte* colonies appear in from four to five days, of a rounded outline with irregular margins, and of a greyish hue. In from twenty to thirty days the whole of the gelatine is liquefied. On ordinary gelose and on glycerinated and peptonised gelose it gives rise to a creamy, moist layer of a faint green tinge. It grows freely on glycerinated potato in the form of a whitish layer which is not dry or scaly and collects at the bottom of the tube. On solid serum it remains invisible, and does not cause liquefaction. It grows freely in amniotic liquid. It does not coagulate milk, but precipitates the caseins, leaving a fatty layer on the surface, with an alkaline reaction. It produces neither pyocyanine nor indol. Most cultures have a disagreeable, but not foetid odour.

The organism increases in length with the age of the culture, and in five or six days becomes thread-like. In ten days it becomes granular and assumes the appearance of the rounded bodies referred to above and met with in plasma, but if at this stage it is inoculated in fresh culture media it reassumes its primitive characters. In thirty days they are all granular and apparently dead, and reinoculations remain sterile, though, with certain precautions and within certain limits, the organism can be brought back to life. The most resistant part of the virus appears to be concentrated in these bodies.

Guinea-pigs into whose peritoneal cavity these cultures were injected died in from ten to fourteen days with paralysis, emaciation, and abortion. Young animals succumbed in twelve hours. Injected beneath the skin it determines the characteristic symptoms, viz., loss of hair and the formation of an indurated, ulcerated *plaque*, with enlargement of the neighbouring lymphatic glands. Post-mortem, the urine is albuminous, the spleen contracted and the liver and kidneys often the seat of fatty degeneration, the blood being invariably sterile. In the frog, death supervenes in thirty-six hours. The sterility of the blood of animals after death recalls the fact that no case has ever been recorded of syphilitic infection by post-mortem wound.

A three days old culture of this organism, placed in contact with the serum of a syphilitic subject with secondary symptoms, determined marked agglutination, a phenomenon which is not produced with the serum of a healthy subject. The inoculation of the cultures in syphilitic subjects remained in every instance without result. Lastly, the alexine contained in the serum of an animal subjected to repeated injections of syphilitic plasma became fixed by this organism, this reaction being due to the intervention of a substance, the special *sensitizer*, engendered by vaccination.

*En resumé* this organism has been found in syphilitic subjects presenting external manifestations of the disease in every case of syphilis examined and in no other cases. It agglutinates the serum of syphilitic subjects and not that of healthy subjects. Experimental inoculation in animals determines special symptoms comparable to those observed in man. It fixes the special alexin of animals vaccinated with syphilitic products, its cultures are without effect on the subjects of syphilis and, lastly, as with syphilis in man, the microbe dies with its host.

On these grounds they affirm that this organism is really the pathogenic organism of syphilis.

### Literature.

#### PARKES AND KENWOOD ON PUBLIC HEALTH. (a)

This is one of the latest, and it may be added one of the best, of the modern handbooks dealing with public health. Both authors are well-known authorities on the subject, and their plan has been to take Dr. Louis Parkes' book, which has run through five editions in ten years, and enlarge and bring it up to date. Some parts of the work we are familiar with, but others appear for the first time. The aim has been to furnish a manual for the use of medical men studying for the various health diplomas, but there can be no doubt that it will be almost equally popular among the profession generally. One chief feature is the ease of style, whereby all essential information is clearly set forth, as it were, *currente calamo*. Yet the work has been conscientiously and carefully done, indeed, the accuracy is most exemplary where such an enormous mass of details is under consideration. In a future edition a little more space might perhaps be bestowed with advantage upon the important subject of meat and meat inspection. Rheumatic fever is mentioned under the communicable diseases with the remark that "there is good reason for believing that this

disease is a specific disease and quite distinct in its origin from ordinary rheumatism. Most authorities are inclined to think that the specific bacterial origin of rheumatism has passed the region of doubt. Cancer, again, which is also alluded to under communicable diseases, might perhaps be more fully dealt with as regards the theories of its parasitic origin. The authors may be congratulated on having produced an excellent book which covers the ground closely enough for all practical purposes within the modest limit of 782 crown octavo pages. The publishing and editing of the volume leave little to be desired, while, last but not least, the price of the book amounts to the extremely moderate sum of twelve shillings.

#### MARTINDALE'S EXTRA PHARMACOPŒIA. (a)

We gladly welcome a tenth edition of "Martindale and Westcott," as the excellent work before us is usually termed. The fact that this is the second edition which has been published since the revision of the Pharmacopœia in 1898 shows the high place which it holds in the opinion of medical men, and entirely relieves the reviewer from the necessity of writing an extensive review. Since the issue of the ninth edition, a new edition of the German Pharmacopœia has been published, as well as an Indian and Colonial Addendum to the Pharmacopœia of 1898, and a Supplement to the Austrian Pharmacopœia. In preparing the present edition, the authors have, "from a pharmaceutical point of view, made a careful study of all these, prepared abstracts from them, and noted the current literature on our subjects." We note that the authors are rather sceptical as to the value of the Indian and Colonial Addendum:—"Many of the pharmaceutical processes in this Addendum appear not to have been tested practically . . . . Some of the drugs, if introduced on their own merits, might prove of service, but we question if many of them will meet with any general recognition even in India or the Colonies." There appears to be a misprint or a possible source of confusion in the head-note to the Therapeutic Index of Diseases and Symptoms:—"The remedies . . . . added in the fifth, &c., editions, are printed in italics . . . . those now added are printed in italics." If this is the case how is the one class to be distinguished from the other. As regards the value of such an index there will probably be a difference of opinion. It may be of use to many medical men, but to us it always appears to be a doubtful advantage in a work of this kind. An index which might be added to the work with great advantage is an index of drugs arranged according to their physiological action—carminatives, diaphoretics, anthelmintics, expectorants, &c. To such an index no exception could be taken, and it would be found to be of the greatest value. We trust that the authors will see their way to make this addition to the eleventh edition of their most valuable work.

#### Dublin Death-rate.

In the Dublin registration area, for the week ending June 22nd, the deaths, which are five over the average number for the corresponding week of the last ten years, represent an annual rate of mortality of 21.3 in every 1,000 of the population. During the twenty-five weeks ending on the same date the death-rate averaged 29.6. In the case of four infants under one year old the cause of death was uncertified, there having been no medical attendant during the last illness. Eighteen deaths of infants under one year old were certified. The annual rate of London for the week was 13.8, Glasgow 19.9, Paris 20.5, New York 17.8.

#### The Preliminary Examination of the Royal Colleges of Physicians, 1902.

We observe from an announcement in another column that material changes have been made in the course for this examination for next year. Intending candidates can obtain all particulars from the secretary, Mr. Greenwood Pim, M.A.

(a) "Hygiene and Public Health." By Louis Parkes, M.D., Lecturer on Public Health at St. George's Hospital Medical School, &c., &c.; and Henry Kenwood, M.B., Assistant Professor of Public Health, University College, &c., &c. London: H. K. Lewis. 1901.

(a) "The Extra Pharmacopœia." By William Martindale, F.L.S., F.C.S., late President and Examiner of the Pharmaceutical Society, and W. Wynn Westcott, M.B.Lond., D.P.H., H.M.'s Coroner for North East London. Tenth Edition. London: H. K. Lewis. 1901. Pp. 32 and 688.

## Medical News.

### Charing Cross Hospital Medical School.

PROFESSOR CLIFFORD ALLBUTT, F.R.S., distributed the scholarships, medals, prizes, and certificates to the students at Charing Cross Hospital Medical School on Wednesday last. The Dean (Mr. Herbert F. Waterhouse) read the annual report, in which reference was made to the services in the South African War of eighteen former students. Dr. Clifford Allbutt, in the course of an interesting address, attributed his own choice of the medical profession to an inordinate curiosity. Curiosity, or the desire to know things, was discouraged by our mediæval methods of education, which taught abstractions in preference to concrete things; but a child who did not show curiosity was probably an imperfect development. Medical students incessantly cultivated the plant of curiosity. Learning from books was not the generation of knowledge, but an accumulation of doubtful value, and there was no more unfortunate relation between pupil and teacher than the former's belief in the latter's infallibility. The scientific method of experimentation made the physician or surgeon not more reckless, but more careful; and in this respect there had been a great improvement during the last thirty or forty years. Heavy bleeding and heavy purgatives were grave experiments, which formerly were made with an ignorant readiness, but nowadays the complicated and delicate machinery of the human body was more carefully treated. A genius was a man who saw something which had not been seen before, and that might happen to any of them.

### St. Mary's Hospital, Paddington.

DR. CHADLE, senior physician of the hospital, presided at the annual distribution of prizes of the students of the medical school. Dr. Caley, the dean, in his report, said that during the past, as in the previous, year many senior students had volunteered for service in South Africa, with the result that sixty-two members of the medical school had been with the Imperial Forces, of whom four had died of wounds or disease. Sir Michael Foster, M.P., who subsequently distributed the prizes, scholarships, &c., delivered an interesting address chiefly with reference to the University of London. Parliament had provided in a crude form statutes for the new university, but they were dry bones which could be rattled. They had no life in them until they were clothed with flesh and blood. With regard to blood they all knew that an essential quality in blood were small round discs of a yellowish colour. (Laughter.) The University of London needed a large and ample transfusion of that sort of blood from without. Passing to the "tissues," Sir Michael pointed out that London was a great manufacturing, commercial, and industrial centre, and it was for the new University of London to show that university and practical knowledge were associated, and always ought to be associated. That was especially so with regard to the medical part of university education, because medicine had a very close relation with the practical life of the people.

### University of Dublin.

At a meeting of the Senate of the University of Dublin, held on June 27th, the following medical degrees were conferred:—

**Doctores in Medicina.**—Alfred Lewis Bartram, Alfred Heathcote Copeman, Joseph Dawson Crawford, Edward Johan Farmer, Harold Freeth, Ernest Blake Knox (stip cond.), Francis Carmichael Purser, Alfred Jacobs Rice-Oxley, Arthur Rhodes.

**Baccalaurei in Medicina.**—Alfred Lewis Bartram, Alfred Heathcote Copeman.

**Baccalaurei in Medicina, in Chirurgia, et in Arte Obstetricia.**—Gerard Irvine Davys, Cecil Edward Finny, Harold Freeth, Thomas William Harley, Francis James Strong Heaney (B.Ch. stip cond.); Ernest Albert William Henley, John William Hilliard, Arthur Norman Holmes, William Davenport Kelly, Ernest Samuel Moorhead, Thomas W. Myles, Thomas George Ferguson Paterson, Richard Atkinson Stoney (B.Ch. stip. cond.); Charles John Swayne, James Arthur Thompson, Jasper Robert Tyrreil.

The following prize and scholarship have been awarded:—Medical Travelling Prize, T. G. Moorhead. Medical Scholarship.—Anatomy and Institutes of Medicine Scholarship, William Boxwell.

### Don Miguel Colmerio.

THE death is announced (*El Siglo Medico*) of Don Miguel Colmerio, Professor of Natural History, Madrid, member of the Royal Academy of Medicine and other scientific societies. To the care and liberality of Don Miguel the Spanish are indebted for the present high state of perfection of the Botanic Gardens of Madrid, and to his many recommendations to the Government and his urgency they are largely indebted for the planting of trees in the principal streets and squares of their chief towns.

### A Botanist Censured.

A LEEDS botanist, who had supplied pennyroyal pills to a woman who subsequently aborted and succumbed to peritonitis, has been "censured" by the coroner, and advised to abstain in future from dealing with medicines of this class. Whatever the abortifacient value of this drug may be, there seems to have been little doubt as to the intention with which they were procured, and it is odd that the jury did not emphasise the "intent."

### Plague in Hong Kong.

DURING the week ending June 22nd there were 155 cases of bubonic plague with 152 (!) deaths in Hong Kong.

### Alleged Mistaken Diagnosis.

AN action was tried in the King's Bench Division last week in which Messrs. Stocks and Crossman, practising in Wandsworth, sued a licensed victualler for fees for professional attendance. The claim was resisted on the ground that the plaintiffs had failed to diagnose a dislocation of the shoulder, the result of a bicycle accident. Inasmuch as it was not denied that a careful examination of the joint had been made soon after the accident, and seeing that the defendant subsequently suffered from alcoholic delirium, during which the dislocation might very well have been occasioned, the jury returned a verdict in favour of the plaintiffs for the amount claimed, they having, in their opinion, "used ordinary and reasonable skill in the treatment."

### Death from Hæmorrhage after Operation.

AN inquest was held on the 25th ult. on the body of a child who had died from hæmorrhage consequent upon removal of the tonsils at the Clinical Hospital, Manchester. It transpired that the child was discharged from the hospital on the day following the operation, and that the bleeding set in on the following day. The child was taken to the hospital again a week later, but it was not thought necessary to detain him. It was admitted that some risk attended the practice followed at the hospital, but it was pointed out that if any complication of this kind occurred it was the duty of the parents to call in a local practitioner, a step which the parents in this instance had apparently failed to take.

### Odontological Society of Great Britain.

THE following members have been elected as Officers and Councillors for the year 1901-1902:—President.—W. A. Maggs. Vice-Presidents.—Resident: A. S. Underwood, F. J. Bennett, W. H. Woodruff; non-resident: G. Brunton (Leeds), W. S. Woodburn (Glasgow), W. B. Bacon (Tunbridge Wells). Treasurer.—C. F. Eilot. Librarian.—H. Baldwin. Curator.—J. F. Colyer. Editor of Transactions.—H. Lloyd Williams. Honorary Secretaries.—J. H. Mummery (foreign), A. Hopewell Smith (Council), W. Rushton (Society). Councillors.—Resident: J. H. Reinhardt, H. G. Read, G. Northcroft, E. Wynne Row, J. Mansbridge, M. F. Hopson, Morton A. Smale, E. D. Pedley, J. Percy Smith; non-resident: D. Corbett, junr. (Dublin), Rees Price (Glasgow), G. O. Whittaker (Manchester), T. Mansell (Birkenhead), W. A. Rhodes (Cambridge), W. Glaisby (York), J. J. H. Saunders (Barnstaple), E. A. Bogue (New York), J. F. L. Pike (Sheffield).

## Notices to Correspondents, Short Letters, &c.

**✉** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

### WHEN DOCTORS DIFFER!

FOUR medical men gave evidence last week in a case at the Brompton County Court in respect of a claim for damages by a woman who had sustained a sprained ankle, caused, she alleged, by falling through a defective pavement light. The medical evidence in effect was:—

First Doctor: All Mrs. Sealy requires is rest.

Second Doctor: Needs two months' massage treatment at two guineas a week.

Third Doctor: Think Mrs. Sealy is suffering from dropsy rather than from the effects of the accident.

Fourth Doctor: All Mrs. Sealy requires is plenty of exercise.

The Jury: £50 damages.

JUNIOR ASSISTANT will find vacancies advertised in our present issue such as he seeks, under the London County Council and the Asylums Board.

STATIST.—Up to June last, 479 medical officers and nine consulting surgeons, 385 surgeons and 441 nurses were despatched to the front. You will find fuller details in the Report of the Hospitals' Commission.

### THE INDIAN MEDICAL SERVICE.

The *Pioneer of India*, of June 28th, in referring to the medical services, says the proposal to absorb the Indian Medical Service in the Army Medical Corps is distinctly unpopular with the Indian Services, and would excite deep and widespread dissatisfaction.

## Diary for the Week.

### ENGLAND.

#### WEDNESDAY, JULY 3RD.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square).—8 p.m. Specimens will be shown by Dr. Lockyer, Dr. Alcock, Dr. Fairbairn and others. Paper: Mr. J. P. Maxwell: On Spontaneous Rupture of the Uterus in Placenta Prævia.

#### THURSDAY, JULY 4TH.

RONTGEN SOCIETY (20, Hanover Square).—8.30 p.m. Annual General Meeting for the Election of Officers, &c. Mr. G. Bowron will show: A Oscilloscope for measuring the Current and Oscillations in the Secondary Circuit of an Induction Coil or similar Apparatus.

ROYAL COLLEGE OF SURGEONS.—Exhibition of specimens added to Museum during past year, in the Council Chamber.

#### FRIDAY, JULY 5TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—5 p.m. Ordinary Meeting. 5.15 p.m. Annual General Meeting.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. Cases. 8.30 p.m. Papers.—Mr. S. Snell: A Case in which Blindness was occasioned by the Internal Administration of Salicylate of Soda.—Mr. J. B. Lawford: Further Notes of a Case of Melanotic Sarcoma of the Conjunctiva.—Major H. Herbert, I.M.S.: Conjunctival Bridge and Pouches; Union of Retrolental Folds.—Mr. S. Stephenson: Wound of Eyeball with Prolapse of Iris, Enuclation of Eyeball Twenty Days after Accident, followed Fifty-three Days later by Sympathetic Disease of the other Eye, Perfect Recovery.

#### SATURDAY, JULY 6TH.

PATHOLOGICAL SOCIETY OF LONDON (Department of Pathology of the University of Oxford, South Parks Road). 3.30 p.m. Laboratory Meeting. Dr. Ritchie: The Relation of Resistance to Tetanus Toxine to Antitoxic Power of Serum.—Dr. Martin: Inhibition of Growth of the Typhoid Bacillus.—Dr. Haldane: Haemoglobinometer.—Dr. Poynton and Dr. Faine: Arthritis produced by Diplococcus Isolated from Rheumatic Fever.—Dr. P. Stewart: Degenerations following Transverse Lesion of the Cord.—Dr. Waters: Demonstration of Tumours.—Mr. Barnard: Calcified Aneurysm of the Renal Artery.

#### TUESDAY, JULY 9TH.

ROYAL MEDICAL BENEVOLENT COLLEGE.—7 p.m.: Festival Dinner at the Hotel Cecil.

SOCIETY FOR THE STUDY OF INEBRIETY (11, Chandos Street, Cavendish Square).—4 p.m. Quarterly Meeting. Papers:—T. N. Kelyack, M.D., and W. Kirkby, F.L.S.: On Arsenical Poisoning from Beer Drinking in its Relation to the Study of Inebriety.

## Appointments.

AUSTEN, HAROLD, M.D., B.S.Lond., M.R.C.S., L.D.S.Eng., Assistant Dental Surgeon to the Dental Hospital of London.  
CADDY, ADRIAN, M.B.Lond., L.R.C.P.Lond., M.R.C.S., Resident Medical Officer to the Parish Infirmary, Brownlow Hill, Liverpool.  
CAMPBELL, P. E., M.B., C.M.Edin., Medical Superintendent of Catterham Asylum, Surrey.  
CRINION, L. A. J., M.B., B.Ch.R.U.I., Medical Officer of Blessington No. 1 Dispensary District in the Naas Union.  
EAMES, E. S. B., L.R.C.P.Lond., M.R.C.S.Eng., District Medical Officer to the Honiton Union.

EURICH, F. W., M.D., C.M.Edin., Pathologist and Bacteriologist to the Corporation of Bradford.  
FARRANT, CHARLES, L.R.C.P.Lond., M.R.C.S., Medical Officer for the St. James's District by the Taunton Board of Guardians.  
GRUGGEN, WILLIAM, L.R.C.P.Irel., L.F.P.S.Glasg., D.P.H.Camb., Medical Officer of Health of Tring.  
HILL, CHARLES A., M.B., B.A.Cantab., D.P.H.Vict., Senior Assistant Physician to the Liverpool Hospital for Consumption.  
HOOD, N. L., M.D., D.C.Cantab., Honorary Surgeon to the York County Hospital.  
LE FANU, G. E. H., M.B.Aberd., Assistant Medical Officer to the Derby Borough Asylum.  
MOORE, S. G., M.B., Ch.B.Vict., D.P.H.Eng.Conj., Medical Officer of Health of Huddersfield.  
RAY, J. H., M.B., Ch.M.Vict., F.R.C.S.Eng., Assistant Surgeon to the Manchester Children's Hospital.  
RIMMER, J. F., M.B., Ch.B.Vict., Third Assistant Medical Officer at Leavesden Asylum, Hertfordshire.

## Vacancies.

Bailborough Union.—Qualified Midwife. Salary £25 per annum. Immediate application to Hugh Clarke, Clerk of Union. (See advt.)  
Carlou Union.—Temporary Medical Officer. Salary £3 3s. per week. Immediate application to the presiding Chairman. (See advt.)  
County Asylum, Carmarthen.—Junior Assistant Medical Officer, unmarried. Salary commencing at £150, with furnished apartments, board, washing, and attendance, without stimulants.  
County Borough of Burton-upon-Trent.—Medical Officer of Health and Public Analyst. Salary at rate of £350 per annum for the Medical Officership and £50 per annum for the office of Public Analyst, and authorised disbursements.  
Cumberland and Westmorland Asylum, Garlands, Carlisle.—Senior Assistant Medical Officer, unmarried. Salary £150 a year, rising to £180, with board, lodging, &c.  
London County Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, washing, &c. Candidates must not be above thirty years of age, and be qualified in medicine and surgery. Forms of application to be obtained of the Clerk of the Asylums Committee. (See advt.)  
London County Asylum, Banstead.—Medical Superintendent. Salary £1,000 per annum with house, rates, taxes, and water supply free. Forms of application to be had of the Clerk to the Asylums Board, London County Council. (See advt.)  
Metropolitan Asylums Board.—Assistant Medical Officers (unmarried) at the Fever and Small-pox Hospitals. Salary £160 per annum, rising to £200, with board, lodging, attendance, and washing. Also Assistant Medical Officer (unmarried) at the Asylum, Caterham, Surrey. Salary £150 per annum, rising to £170, with rations, lodging, attendance, and washing. (See advt.)  
North Wales Counties Lunatic Asylum, Denbigh.—Second Assistant Medical Officer. Salary commencing at £120 per annum, with board, residence, and washing.  
North-Western Fever Hospital, Lawn Road, Hampstead.—Locum Tenens. Salary at rate of £160 per annum, with board, lodging, and washing.  
Owens College, Manchester.—Senior and Junior Demonstrator in Physiology. Stipends £150, rising to £200, and £100 rising to £150 respectively.  
Plymouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200 per annum, with furnished apartments and board and washing.  
West Riding Asylum, Wadsley, near Sheffield.—Third Assistant Medical Officer, Salary £150, with board, &c., rising to £200. Also Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c., rising to £180.

## Births.

HILLS.—On June 25th, at New Bridge House, Upwell, the wife of W. C. D. Hills, M.B.C.S.Eng., L.R.C.P.Lond., of a daughter.  
KEMP.—On June 24th, at Worktop, Notts, the wife of G. Lajus Kemp, M.D.Lond., of a son.  
KNAGGS.—On June 24th, at Camden Road, London, N.W., the wife of H. V. Knaggs, M.B.C.S., of a daughter.  
MANNINGTON.—On June 24th, at Belmont, Muswell Hill Road, Highgate, the wife of Frank Mannington, F.R.C.S.Eng., of a daughter.  
WYNDHAM.—On June 27th, at Goring-on-Thames, the wife of T. Lancelot Wyndham, L.R.C.P., L.R.C.S., of Bromley, Kent, of a daughter.

## Marriages.

BARLOW—PONSFORD.—On June 27th, at Stanford Parish Church, Kent, Herbert Cecil Barlow, M.B.Lond., L.R.C.P., M.R.C.S., of St. Ives, Farnborough, eldest son of the Rev. T. Disney Barlow, of Blaby, Leicester, to Muriel, second daughter of the late Rev. W. Ponsford, late rector of Stanford, Kent.  
DYBALL—KNIGHT.—On June 27th, at St. Mark's Church, North Audley Street, London, W., Brennan Dyball, M.B., B.S., F.R.C.S., of 47, Queen Street, Exeter, to Evelyn Maud, youngest daughter of Sir Henry E. Knight, of 41, Hill Street, Mayfair, and Stain Hill Park, Hampton.  
GALLWEY—GORDON.—On June 22nd, at St. Patrick's Church, Soho Square, by the Rev. Dean Vere, Colonel Sir Thomas Gallwey, B.A.M.C., to Maud Margaret Howard, widow of the late Captain C. W. Duff Gordon, Royal Artillery.  
WATSON—RANKIN.—On June 27th, at St. Andrew's Church, Boshford, George Trustram Watson, M.A., M.B., B.C.Cantab., F.R.C.S., of Hastings, to Dorothy Nora, eldest daughter of Hugh Rankin, Esq. J.P., of Boshford, Essex.

REMARKS ON THREE CASES  
ILLUSTRATING

### DIRECT INFECTION WITH THE BACILLUS TUBERCULOSIS. (a)

By STANLEY BOYD, M.B.Lond., F.R.C.S.,

Surgeon to Charing Cross Hospital and the Brompton Hospital for  
Consumption and Diseases of the Chest.

CASES of direct infection with the bacillus tuberculosis are very interesting, but they are by no means common. In many cases there is nothing to do but theorise as to how infection takes place. For example, bacilli are found in the bronchial glands; on searching through the lungs very carefully, and through the mucous membrane of the respiratory passages draining to the bronchial glands, no lesion may be found. How, then, did the bacilli get to these glands? It is inferred that they passed through the mucous membrane of the pulmonary tract somewhere or other, leaving no primary lesion at their point of entry, or if there was any little disturbance during their passage, that it completely subsided, and left no post-mortem evidence. In the following cases there is no need to theorise at all; the inoculation of the bacillus tuberculosis at certain points in man is clear, and in one of the cases the course of the disease can be followed most admirably.

The first case now shows nothing beyond a normal scar. It was that of one of the nurses, who, in March or April, 1900, was carrying a tray of used spittoons; she fell, and a broken spittoon made a clean cut on her left wrist in front of the radial artery. It healed readily, but not soundly. In about a fortnight the dressing was taken off, and a scab was left. When this was removed a little central hole was found in the scar, and from and around this, redness and infiltration of the skin slowly spread. The soreness then became more marked, and the central hole remained until August. At that date she had an area of thickened skin the size of a fourpenny piece, red, dry, and somewhat warty on the surface, with a well-defined edge. The glands were not affected, and there was no evidence of spread of the infection to the lymphatics of the forearm; the whole case would be summed up by saying that she had an inflammatory thickening of the skin at this spot. On cutting it out completely, and bringing the edges together, the little wound healed by first intention, and she is now perfectly well, and has had no trouble since. Microscopic sections showed that the disease was the result of infection by the tubercle bacillus.

The next case, a lady whose age was about thirty-five, had been suffering for many years from chronic phthisis in the right lung. During an exacerbation

of her phthisis—with much expectoration, which she always received upon a handkerchief—she caused a slight abrasion with a lump of sugar on the extensor aspect of the first phalangeal joint of the right index finger. That abrasion never healed, and, although no microscopic examination was made of any of the parts removed, the clinical course renders it practically certain that this was because tubercle bacilli were inoculated from the handkerchief upon the sore. For some months no attention was paid to the sore; finally, she saw a surgeon, who rang the changes on cod-liver oil and iron, and iron and cod-liver oil. That went on for a considerable time, and no improvement took place; on the contrary, the disease was spreading in a most characteristic way. The first thing noticed was, that some months after the infection a considerable swelling formed somewhat acutely in the situation of the internal supra-condyle glands. Probably there was a mixed infection of the glands, septic or pyogenic as well as tuberculous. No suppuration occurred, however, and after a time these swellings subsided, though not completely. Next she noticed an elongated patch of infiltration just below the elbow, over which the skin was adherent and reddened round the radial lymphatics. Next a similar patch formed on the dorsum of the hand, over the second interosseous space, which ulcerated slightly. The last result the patient noticed was a small mobile lentil-like subcutaneous nodule on the ulnar side of the olecranon process; it seemed obviously to be in some lymphatic vessel. She had in addition two or three enlarged lymphatics behind the pectoral muscle. This case shows the way in which tubercle spreads by the lymph path from an evident primary lesion to the first and second group of glands above it, and, what is uncommon in the skin and subcutaneous tissue, there were here and there in the course of the lymphatics small foci of tuberculous lymphangitis, due to arrest and growth at these spots of bacilli. It is interesting to note that they did not appear until after the lymphadenitis, which probably slowed the circulation in some lymphatic vessels.

Under ether the edges were excised and the base of the primary lesion scraped, pure phenol was applied, and the wound dressed with iodoform. All affected glands, patches, and nodules were excised. Everything united by first intention except the finger; that did not heal, in spite of frequent and free applications of pure carbolic and iodoform. Ultimately it was completely excised. It then healed slowly but soundly—some sixteen months after the first operation. During most of this time fresh little shot-like nodules kept appearing along the course of the radial lymphatics. One by one they were excised under cocaine, seven or eight such operations being done. Once or twice an operation was repeated for recurrence *in loco*, possibly because the first excision was incomplete, for after the production of cocaine oedema all evidence of the little

(a) Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.

nodule, to sight or touch, was lost. The patient, fortunately, was plucky and determined, for the course of treatment was long and especially trying to one in feeble health. She has now been free from recurrence for more than eighteen months, although she has had pleurisy and some advance of her chest trouble.

The lessons to learnt from these cases are :—(1) That timely excision of tuberculous sores is the proper treatment, and (2) that with patience and perseverance the disease may be arrested even where it has got a long start. It is, however, only fair to point out that in the second case the patient, though liable to tubercle, was evidently resistant in a fairly high degree.

The next case is one of direct infection of a tendon-sheath with tubercle bacilli in the person of the post-mortem porter (æt. 62) in this hospital, whose duty it is to stain the sputum for examination. After employing a steel pen to spread some sputum known to be virulent, upon a cover-glass, he left it projecting beyond the edge of the table, and brought his hand forcibly against its point. The nib was driven into the proximal end of the flexor sheath of the ring finger. This occurred in the middle of June, 1900. He immediately tried to run fuming nitric acid into the wound caused by the pen, and no doubt he disinfected the surface by that means, but not the depths. A hard lump gradually formed in the palm, and extended down along the ring finger, which became flexed, stiff, and painful. He was treated by means of a palmar splint, and was sent to Brighton for some weeks, but he got no better. The finger became contracted, and the middle and little fingers also were coming down into the palm. A long, low, tense swelling occupied the whole length of the flexor sheath of the ring finger. The diagnosis was obvious; it was a case of tuberculous teno-synovitis. The treatment was equally clear. The man had had the advantage of the best hygienic condition which could be provided for him; he had been to the seaside with nothing to do except to look after himself and get well, but he had got steadily worse. The complete removal of the disease was urgently necessary. Six months after the operation extension of the finger is somewhat limited by the long longitudinal scar on its palmar aspect, but he has fair and very useful movement, and he is perfectly free from recurrence. The prognosis of tubercle gets worse as age increases, and therefore this result may be considered very satisfactory. A section of the granulation tissue removed shows "giant-cell systems" in large numbers and great perfection.

## TYPES OF INDIGESTION AND THEIR WIDE CORELATIONS.

By WILLIAM H. PEARSE, M.D. Edin.,  
Senior Physician, Plymouth Public Dispensary.

In an out-of-door dispensary view and treatment of disease, though we lose the advantages and control of the diet, of the exact administration of drugs, of the minute watching of the course of cases, and of the final post-mortem revelations which hospital practice gives, yet, on the other hand, we see disease over a wider area, in its inception, evolution, and gradations; we see disease in the delicacy of blendings and corelations; a dispensary clinique takes us towards the springs of the more final forms or streams—the nomenclatured diseases. A love for the out-patient room of the hospital will not a little aid in teaching the student—young or old—the largeness of the field of medicine, and prevent a

calamitous conviction of the completeness of his knowledge. A geologist or botanist does not, in general, expand to his sciences if he confine his work to books and museums; he is greatly benefited and expanded by wide field excursions; the out-of-door clinique may be looked on as a field excursion into the regions of disease.

I do not know any field more educational and expanding toward wide and just generalisation than that presented by the very complex and widely correlated symptoms which come to us under the name of Indigestion.

This is not only true in relation to symptoms and their varied corelations, but no less so in relation to the profound and varied physiology and pathology of the great organic vital tract, extending from the mouth to the rectum. The very foundations of the living cell and animal are involved. But although we cannot yet solve the complex bio-chemical problems involved in Indigestion and in its disturbances, yet a great and good empirical knowledge and practice may be attained.

I propose to view Indigestion on the side which is presented in actual practice, and not to attempt the difficult and complex bio-chemical study. For this purpose I have gone over my notes of fifty-four cases occurring during the past five years.

Niemeyer says :—"Jaksch and others have given us statistics of its (chronic ulcer of the stomach) frequency at different ages, and in different employments, &c. In the accounts of 2,330 post-mortem examinations, Jaksch found round ulcers mentioned fifty-seven times, so that to about every twenty bodies there was either an ulcer or a cicatrix. Milligan, Brinton, and others, come to similar conclusions."

Such a proved frequency of ulcer of the stomach will always compel the most serious attention to seeming trivial complaints in young adults, involving pain at the epigastrium after taking food, vomiting after eating, &c., but, on the other hand, the great number of young women who come with epigastric pains after eating, and which are relieved by vomiting, and the rapidity with which most of such cases recover has forced me to view the greater proportion of the seeming cases of ulcer of the stomach as neuroses, and I have been the more forced to this view because such seeming chronic ulcers of the stomach have wide and varied general correlated or associated disturbance of other functions. The epigastric pain and vomiting bring the patient, but the doctor will at once see that there often exists a wide and varied disturbance of different functions, which appear to be in part the foundation or essential corelatives of the stomach trouble. The rapidity of recovery of many, under a treatment not mainly directed to the stomach, but toward correcting or balancing general conditions, seems to confirm my impression that often these cases, with the most pronounced symptoms of pain at the epigastrium after eating, and which is relieved by vomiting, are neuroses.

In young women, at the period of the full evolution of their being, we can never afford to overlook the waywardness of a great variety of neuroses, with symptoms as "variable as the shade by the light-quivering aspen made."

I will shortly summarise the symptoms of the series of cases now under analysis; we shall be carried, both in the causation and corelations of Indigestion, not a little away from the stomach into wide general conditions; and such should have a due influence on our treatment.

*Type of Pain.*—In the fifty-four cases, most referred the pain to the epigastrium only, eight to the epigastrium and back, eight to the epigastrium

and left infra-axillary region, two to the epigastrium and sternum, three to the sternum only, and one to the left I.A.R. only. Such a wide area of pain, and involving nerve distribution from the medulla, the dorsal spinal cord, the great solar plexus, &c., carries us into wide correlations, and helps to correct that narrowing finality of pathology which the words gastric ulcer tends to foster.

Thirty-five said that the pain came on immediately after eating, two in five minutes, seven in ten minutes, one in fifteen minutes, five in thirty minutes, and three in one hour after eating.

Of those recorded, the pain lasted half an hour in three cases, one hour in six cases, two hours in nine cases, "hours" in three cases, and all day in five cases.

Vomiting was present in thirty-four cases; ten vomited blood, twenty-two "bitter" (bile?), and nine "sour." Twenty cases said that vomiting gave relief to the pain, four said that the pain was relieved by belching wind, two said that the pain went off by itself.

All the fifty-four patients were females: thirteen cases were in those between 14 and 20 years of age, nineteen between 20 and 25, ten between 25 and 30, three between 30 and 35, four between 35 and 40, two between 40 and 45, and three between 45 and 50.

We know that gastric ulcer mostly occurs in young women; but on the other hand, when we remember the vast "potential" of "energy" involved in the stomach and its related nerves and glands, transforming in the earlier stages crude food into living bioplasm, and doing this throughout a whole lifetime,—we shall be prepared to expect the nerve centres of the stomach to show a great variety of neuroses; we might fairly expect that the symptoms of gastric ulcer and of the varied neuroses would often commingle and not be distinguishable with any certainty.

Fourteen of the cases showed other well-marked neuroses or neuralgias; two were anæmic, one had urticaria, and five had a family history of phthisis. I have on former occasions shown that Indigestion is correlatable and often atavic with phthisis.

The menses were natural in twenty-two cases, absent in four, scant in four, profuse in one, congenitally absent in two.

There was thus not much disturbance of the menstrual function, not much correlation between the Indigestion—ulcerative or neurotic—and the menses.

The bowels were costive in twenty-nine cases, extremely costive in two, natural in thirteen. By costive is meant an action once in from three to five or six days. This costiveness seems to be very fundamental in such cases; it is remarkable that the great organic tract should be deficient in energy and function in young women, coincident with the evolution or development of the body in general, with the evolution of the sexual and nervous systems, with, in short, the evolution of the fuller being of the individual. The deficient action of the organic *primæ viæ*, thus coincident with and correlating with the general full evolution of the individual, has its roots in the widest general conditions, in the conditions of the blood, cells, and nerve energy of the general bioplasm and nervous system; on the other hand, the deficient action of the great glands and organs of the *primæ viæ* reacts injuriously on the whole system—blood, cell-contents, and nerve centres; the costiveness, the inadequate action of the *primæ viæ* is part of a vicious circle; other parts of that circle are the Indigestion, the fæcal smelling breath, anæmia, palpitations, &c.; in somewhat figurative language, the whole system seems poisoned by a somewhat suspended metabolism of the organism. The word "costiveness" is apt to close our

view from the wide and deep generic causation and correlations of the symptom.

In a large proportion of the cases where the Indigestion is associated with sluggish *primæ viæ* and anæmia, the ancient pil. aloë. et fer. taken at bedtime, or on alternate nights, as needed, followed in the morning by a moderate draught of Carlsbad or Fredrickshall water, will effectually restore the patient, and the indigestion and seeming ulcer of the stomach will, in many cases, vanish. I usually advise the juice of a third or half a lemon to be drunk in warm water at bedtime, or the lemon juice may be squeezed over the food at meal times. The lemon juice is far best taken without sugar. (a)

I am not here stating orthodox rules for the treatment of established gastric ulcer, but indicating general principles applicable to a great proportion of those with epigastric trouble and its correlated conditions.

*Wasting.*—Out of the fifty-four cases, two were appreciably wasted. Even in chronic cases, with vomiting of food nearly every day for a year, the patients have not been appreciably wasted.

*Duration of Cases.*—Two had been ill, off and on, for six years, two for five years, one for four years, three for three years, one for two and a-half years, three for two years, one for one and a-half years, and eighteen for one year, one for eight months, six for six months, one for four months, eight for three months, one for two months, six for one month, and one for one week.

*Intervals of Acuter Attacks.*—Acuter attacks in the course of chronic cases usually happened with intervals of from a few weeks to from three to six months. Thirteen had had former acuter attacks; eleven of these had had two or three or several acuter attacks.

I cannot, with a confident finality of diagnosis, assert that the above-stated series of cases were "chronic gastric ulcer"; the neurotic type was often very obvious, and one is far more impressed with this view when in contact with the patients, than any description can convey; there exists, if I may so term it, a peculiar *aura* round about neurotic cases which no words can express, but which is very light-giving in diagnosis. The true Artist catches a something in the scene which is the soul of his picture, but which cannot be described; and so it is with the evolving neurotic young woman; the essential diagnosis lies in a general estimate of many symptoms, which the physician instantly observes, and rapidly and rightly generalises. The right diagnosis and treatment of many cases of Indigestion in young women, will make one feel the force of Herschel's words that, "humility of pretension and confidence of hope become the true philosopher," and physician.

As examples of rapidly relieved cases, A. P., f., set. 40, said that for two years she had suffered pain at the epigastrium after taking food; the pain came on one hour after eating, and lasted two or three hours: then she vomited and found ease; the vomit was bitter; she was very costive. I ordered a mixture of bis. carb., soda bicarb., and lactopeptine; also Fredrickshall water in small doses, to be drunk diluted with warm water, daily before breakfast. In three days she was well, and has remained well.

Miss C., set. 25, a schoolmistress, said that for three years she had suffered pain at the epigastrium after taking food; the pain came on one hour after

(a) Eastern people are far more intelligent than are Western in matters of food and drink. It is quite common in the West to find ladies who think—often, alas! having been told so—that the "mucous membrane of their stomachs are so delicate" that they dare not eat raw fruits or adequate vegetables! It is difficult to conceive a Native of India refusing to use lime juice, tamarind, or other fruits. The experience of thousands of years has made the Native wise in many of the great matters of health and life.

eating, lasted one hour, and was felt also in the back; the pain frequently passed off with belching of wind; she suffered pain also in the right supraorbital nerve; she said that she had been anæmic a few years ago. Menses regular, not costive. I ordered a mixture of muriatic acid, quinine, tinc. calumb, and tinct. zingib. fort. Meeting this lady three years afterwards, she told me that she was quite well in three days with the use of the medicine, and had remained well since.

The first case was probably mainly relieved by the Fredrickshall water restoring an activity of the whole tract of the *primæ viæ*. The complex yet harmonious molecular constitution of the natural mineral water seemed to have given, through the great intestinal tract—the fundamental *primæ viæ*—a renewal of active “energy” to the bioplasm of the whole system. In the second case perhaps the mineral acid, tinctures, and quinine stimulated the actions and functions of the stomach; but here, too, the drugs must have acted through the whole bioplasmic and nervous systems. It appears to me wiser to submit to such vague and general hypotheses than to assert a dogmatic and verbal finality of a bare chemical therapeutic action and cure, or one based on a germicidal cure. The Indigestion in neither of the cases was an affair of the stomach; we have to cast our view far around in biology and pathology for the true connections and correlations of the most “simple” (P) cases. Nor should I exclude, in the relief of such cases, the “mental therapeutics” of the physician who brightly lifts the mental modes of the patient into the realm of hope.

These two cases are taken from a long list of similar ones. I should in such, and other cases in general, tell the patients never to look at the often pernicious printed sheet of what they may, and may not eat, for these printed diet sheets too often tend to keep the patients' mind in a state of anxiety, suspense, and needless worry. As a very general rule the patients should eat what they most fancy, and what they find to agree, not excluding vegetables, potatoes, fruits, and often with great advantage they may take pickles and malt vinegar.

I would illustrate the generic type of Indigestion, and the general involvement of the whole system by an abstract of a few cases.

L. C., f., æt. 15, had never menstruated; was a tall, pale girl; for over a month she had suffered pain at the epigastrium, coming on half an hour after eating, and lasting one hour; the pain usually “went off of itself,” but on some days she vomited.

G. T., f., æt. 35, had very profuse menses, which appeared every two weeks; extremely costive. For four months has had pain at the epigastrium, which lasts two hours, immediately after eating; then follows bitter vomit.

In these two cases the indigestion correlated with disturbed menstrual function, and both cases were probably neuroses.

S. G., f., æt. 45, had had a large family; had nursed her children; was a fine-limbed and mentally superior type of woman. For six months had suffered from severe pain at the epigastrium after eating, the pain extended around the left side and over the lower dorsal vertebræ. Under ammon. bromide and t. cinchonæ co. she was quite well in three weeks, and has remained well for two years. Liberal and varied diet was allowed. In lieu of a restricted milk diet, or of any “special brand” of whiskey, wine, or stout, I ordered her to take a walk out daily in the sea-breezy park.

M. G. M., f., æt. 47, had pain at the epigastrium immediately after eating, and which lasted from three to four hours; then she vomited “sour;” always costive menses; appear once in about six or eight

weeks, never had bleeding piles. She said that she never suffered indigestion until she received a great shock, her son being killed in a railway accident. It is impossible to exclude the “shock” as a very real part of the complex and wide correlations of this woman's “indigestion.” The case seems light-giving and suggestive as to the great place of nerve influence.

M. F., f., æt. 27, an intelligent, well-grown, single woman, said that for several years, on and off, she had “burning” at the epigastrium “like a coal of fire.” Is well, now and then, for weeks together. For two years past the epigastric pain and burning have been pretty constant; the painful sensations are worse after food. She says that the “burning” at the epigastrium is a good deal relieved if she make her corset press in and “support” that region. Is not costive; menses regular. I have treated this case on varied orthodox drug paths without much benefit; she also has at times been on a restricted milk and rice diet. I have also used with her the most encouraging “mental therapeutics.”

I dare not “magisterially assert on nature” in this case; but am more inclined to view the symptoms as neuroses rather than “chronic ulcer.”

A. N., f., æt. 23, a refined and intelligent woman, of nervous temperament, said that she did not “run off” till she was six years old; she had suffered pain at the epigastrium and in the left side of the abdomen during the past eight years. Seven years ago she was treated in a London hospital for gastric ulcer. The pain comes on at once after eating and lasts all day; the pain also comes on when she gets up in the morning. Is costive; vomits “sour,” and sometimes “bitter”; has sour taste in her mouth; has never vomited blood; belches with flavour of rotten eggs. She is worst at the monthly periods, but is quite free from “indigestion” when pregnant; has had three children. During eight months I treated her with various drugs—bismuth, lactopeptine, and cocaine; also with combined muriatic acid and pepsine; also byzini. The bowels were kept open by pil. rhei. co., and sometimes by Carlsbad water. The diet was sometimes restricted to milk, rice, custards, &c.; at other periods a freer diet of fish was given. The patient would now and then be better for a week or two, but relapsed. My eight months treatment was unsuccessful. It is fair to say that this woman had chronic gastric ulcer or gastric catarrh, but these words or names are apt to have an unjustly narrowing influence on our pathological conceptions. Her rickety childhood, her refined type, physically and mentally, the indigestion being worse at the monthly periods, its absence during pregnancy, all point to the widest and most general neurotic base. Though obliged to carry out the orthodox treatment, I did not omit more general means, such as making her go out for a walk daily, and sending her off for some weeks for change of air. The case certainly enlarges one's view of the wide correlations of indigestion, neurotic or ulcerative, and does away with the narrowing limits which names are apt to impose.

M. E., f., æt. 19, a well-nourished, spirited country girl, came for pain at the epigastrium lasting two hours after eating, then she vomited “bitter and sour,” with relief to the pain; very costive, menses regular. She said that she had suffered “indigestion” for two years, and that it followed after a “fit.” She never suffered prior to the fit. Another young woman, æt. 20, had been three years under different medical men, including three months in hospital on an exclusive milk diet. She vomited, more or less, frothy blood two or three times a week. No treatment gave relief. She said that her illness commenced shortly after her tonsils were excised. I

should be very far from pooh-poohing a possible causation between the excision of the tonsils and her subsequent stubborn disorder of the functions of the stomach. The tonsils have great, and as yet unknown correlations to the entire system, nervous and bioplasmic. I think that the beautiful guillotine is far too often used.

A woman, æt. 25, had noticed a correlation between her frequent attacks of urticaria and the epigastric trouble.

The following case lately under observation seems light-giving. R. S., f., æt. 34, a refined and conscientious type of woman, said that for three years she had suffered pain at the epigastrium, which came on one hour after eating; it was a "sinking" and "gnawing" pain; now and then the pain was sharp, and extended round the left side and over the lower dorsal vertebrae. The pain lasted two or more hours; the pain went off associated with rumbling in the bowels, the pain could be relieved by eating or lying down. Costive, and occasionally vomits "bitter." I ordered a mixture of acid. mur. dil., ℥ xv., liq. morph. mur., ℥ v., glycer. pepsine, ℥ xxx., to be taken three times a day after meals. She could take any food she preferred, and take tea if she liked. The patient was entirely relieved before the end of a week's treatment, and has remained well.

Trousseau taught us the value of small doses of morphine in combination with muriatic acid. But to venture an hypothesis, may I say, as an explanation of the success of such treatment, that the morphine would allay pain and hinder secretion, thus resting the secretory cells and their nervous mechanism. Meanwhile, the muriatic acid and pepsine would carry on digestion, and the organism would not suffer from the defective nutrition consequent on the non-digestion of sufficient food.

Improved nutrition would react on the secretory cells and help their recovery, so that they could soon resume their normal activities.

The examples will, I hope, be of use in showing the width of pathological relations of "Indigestion"; treatment also must embrace a wide general view; no disease, more than epigastric indigestion, opens to our view the widest correlations and interdependence of function, both in health and its disturbance—disease.

During over twenty years' wide observation I have not known of a case of fatal gastric ulcer.

#### TREATMENT.

In a hospital we see disease in its more final stages and forms; in hospital cases and practice, gastric ulcer is usually easily recognisable, and, no doubt, the orthodox treatment of the day, rest, opium, exclusive milk diet, ioe, &c., is called for, and in our present light, right; but in dispensary practice we often see disease in its evolution and growth, in the delicate deviations of its onset, and in the wide deviations of its earlier roots. Thus it happens that orthodox and routine rules of treatment will not be a measure of, or meet the conditions of, the varying types of cases which nature presents.

In thirty-four of my cases of indigestion I began treatment with muriatic acid, quinine and pepsine; the greater proportion did well, but in thirteen of the above I had to abandon the treatment and to give bismuth, sodæ bicarb. and lactopeptine; even then, in several, I failed to give relief. Malt extract was given under both classes of treatment. In eleven, I began with and continued the bismuth, &c., treatment. I have seen, in a few cases, a rapid relief both from the acid and bismuth treatments, but in some cases there was much failure to relieve the patients.

A paramount aim was to greatly stimulate the whole *primæ viæ* by the pil. aloë et. fer., or by a

mineral water, by a digestible but varied diet; by the use of lemon juice as a drink. In a few that I kept on an exclusive milk diet, temporary benefit would happen, but in general the patients were not "cured" by a milk diet, the relief of the pain would be for a week or two only. I incline more to a light and varied diet—fish, the best vegetables, and fruits. I am sure that lemon juice, drank daily in cold or warm water, is a mighty good thing, both for the young and old. The semi-scorbutic, anæmic, vitally expended Native of India will beseech that he be given lime juice or tamarind; under its use his ulcerative chronic diarrhoea and dysentery will often cease; his whole system will be benefited, and thus, his bowel complaints will cease, and, presumably, the extensive ulcers of his big gut heal. It is a most limited view of pathology and of therapeutics to treat the Natives' dysenteric-diarrhoea by remedies directed to the bowels only; his dysenteric-diarrhoea has a deep-down generic base; similarly, the young women of the poorer classes in South Britain, whose action of the *primæ viæ*, as shown by costiveness, by the fæcal fœtor of the breath, by the often coexisting anæmia, by the indigestion, by the chlorosis, &c., must be treated on the widest general principles.

Both in the Natives of India suffering from extreme loss of appetite, anæmia and often chronic diarrhoea, and with young Europeans suffering from epigastric pains, sluggish action of the *primæ viæ*, I have a great many times put them on the right path towards recovery by yielding to their fancies for special food; "sours," i.e., vinegar, pickles, lime juice, tamarind, &c., may often be given with great advantage, especially when asked for. I have often seen patients who have been kept on a strict and limited diet, e.g., milk, mutton, &c., and who have been debarred fruits, vegetables, onions, tea, &c., get well almost at once on giving them a greater liberty. I never ignore the possibilities of neurotic influences in "indigestion," and aim to look all round for the correlations and greater channels of the case.

No one would lose sight of the beautiful researches of the bio-chemists and physiologists on the great organs and glands of the organic tract; but there is another field for the observant practitioner, viz., the experience of mankind throughout the ages, and, when judiciously interpreted, the expressed desires of our patients. Empiricism, submissively observed and carefully studied and sifted, is often a right path for safe practice.

## THE OPERATIVE TREATMENT OF DEFORMITIES OF THE ELBOW-JOINT RESULTING FROM TRAUMATISM. (a)

By DR. SAMUEL LLOYD,  
Of New York.

THREE things were recognised in fractures into the elbow-joint: First, it is not always possible to tell, even under an anæsthetic and with the most careful examination, just what the joint injury is. Secondly, it is not always possible to replace the fragments, even approximately. Thirdly, ankylosis will result in certain cases in spite of any plan of treatment that may be adopted.

All fractures involving, or in the vicinity of the elbow-joint, should be examined under anæsthesia,

(a) Abstract of paper read before the New York Academy of Medicine, April, 1901.

the fragments placed in apposition, and the limb dressed in a position that enables the operator to retain them in place most efficiently. Personally I prefer flexion. I am decidedly opposed to passive motion, so much advocated by the older surgeons, believing that this caused an increase of callus and consequent diminished range of motion. Any passive motion in an elbow-joint, until after the bone is firmly united, is meddling surgery. If, when the splint is removed, motion does not return promptly by active motion (an attempt on the part of the patient to use it regularly), the deformity should be examined. If moderate passive motion succeeded, then we have to do with simple adhesions. If the joint does not yield under an anæsthetic, then the difficulty is probably due to obstructing callus or to a displaced fragment. I believe the ankylosis or limitation of motion to be due to bone and not to fibrous adhesions, provided there have been no septic complications. While my first operations and conclusions antedated the use of X-rays, they have been corroborated by an extensive use of the X-ray.

The overproduction of callus is a constant danger in the direction of producing ankylosis, and is increased by any motion of the fragments during the period of union. Provisional callus is objectionable. The bone unites in the same manner as the soft tissues, with but little granulation tissue, if firmly held together.

The X-ray has been somewhat disappointing in solving all the difficulties of fracture work, since it gives only a shadow of the real object. The X-ray, however, so frequently illustrating dislocation complications has emphasised the necessity of using an anæsthetic in the first examination of fractures about the elbow-joint.

The majority of cases of ankylosis of elbow following fracture being due to bony displacement or to callus, if non-operative measures are not successful in removing these causes, something should be done to put the bones in proper position. In compound fractures we are all agreed as to what should be done—viz., enlarge the wound and suture the fragments in position.

It is, however, on simple fracture that I would dwell more particularly. At first sight cutting into the joint and manipulating the structures about the joint, including the capsule, would appear likely to result in almost, if not absolute, fixation. Such has not been my experience, and I hold that the fear of attacking a joint surgically is largely a relic of pre-septic times.

I am enabled to illustrate the different fractures occurring in vicinity of the elbow-joint by a series of skiagraphs of cases I have operated upon. One is a supra-condyloid fracture of the humerus where the difficulty was found due to both callus and displacement. The arm had been treated at an angle 145 degrees, the condyles being carried backward while the shaft of the bone was drawn forward.

In flexion the coronoid process of the ulna struck upon the mass of callus below the more prominent projection of the shaft, while the ulna rested upon the sharp end of the diaphysis in the complete flexion. This boy had a useless arm. The projecting portion of the diaphysis was chiselled off and a new coronoid fossa was cut out with a curette until complete flexion was possible. The result was remarkably satisfactory. In spite of the extensive dissection necessary to reach the anterior surface of the humerus and the consequent lacerating and bruising of the capsule and synovial membrane, flexion was obtained almost to the full extent. The other skiagraphs further illustrate varieties of fractures about the elbow-joint, complicated with callus and dislocation, upon which I have operated gene-

rally with success. I may sum up the management of fractures of the elbow in the following words:—

(1) Examination and reduction under ether. If the latter is impossible, and it is evident that disability will result in consequence, immediate incision and dissection until the fragments can be forced into position and wired or sutured. If, however, this is still impossible, the fragments should be removed.

(2) If ankylosis or marked limitation of motion results and does not prove to be due to fibrous bands, operation should be undertaken and everything opposing the proper movement of the joint should be cut away.

When I performed my original operation in 1894, I was unable to find any records of previous operations of the kind, but now there are many. I may mention as reporting cases, Alles, "Annals of Surgery," 1897; Wight, *ibid.*, 1893; Klemm Sambheng, "Klin Vortrag," Sept, 1893, recognised possibility of the operation.

The open method of treatment was advocated much earlier in irreducible dislocations of the elbow, and it seems strange that it was late in coming into more general use in fractures.

In all my cases, twenty-one in number, the posterior incision similar to that made for excision of the joint was employed. This answered well for manipulation of the olecranon fossa of the humerus or the injuries to the condyles. The difficulty of clearing out the coronoid fossa and managing the anterior displacement was greater. I varied the incisions according to the injury. The capsule should be as carefully opened and sutured as the peritoneum. One can scarcely be too radical in removing bone; it is better to try for both flexion and extension than to stop short of removal of any obstruction. After removal of bone I flush the joint with hot normal saline solution, suture the capsule carefully, and close the wound without drainage. Rest in flexed position for one week, then massage and active motion.

## TUBERCULOSIS IN CATTLE:

### ITS SPREAD AND PREVENTION. (a)

By MR. J. P. PENBERTHY, F.R.C.V.S.,

Professor of Medicine in the Royal Veterinary College, London.

THE lecturer remarked that during the past twenty years much scientific knowledge of that disease had been acquired, but the application of scientific knowledge was not likely to be far in advance of public opinion. The value of educating the public on that subject could scarcely be over-estimated, for science had done its share by demonstrating its preventibility and the means of prevention, but the suppression of that menace to human health and agricultural prosperity must now remain with the public, whom it affects. It was now for the social economist and the legislator to apply the knowledge science had placed at his disposal. It was, however, "the man in the street" whose expressed opinion set in motion the cumbersome machinery of social economy and legislation, and he was firmly convinced that it was to the education of the public they must look for the removal of that deadly enemy. A single case of suspected plague, cholera, or small-pox, was reported with the utmost alacrity throughout the length and breadth of the land, and stringent measures were immediately adopted for preventing its spread. Diphtheria, measles, scarlet fever, &c., were all provided for by law as they might reasonably expect. Tuberculosis claimed annually for its victims in Great Britain and Ireland about 70,000 human beings—one-tenth of the total mortality in these islands, and yet, until within recent years it was allowed to pass unchallenged, and was still practically unlegislated for. That inaction

(a) Abstract of lecture delivered at Aberdeen at the instance of the Committee on Tuberculosis.

had resulted from several causes, the chief of which was the insidious progress of the malady, want of knowledge, and, beyond all, the absence of any evidence that it was preventible. Scientific men, as witnessed by their work and words, politicians, as proved by the appointment of committees and Royal Commissions, recognised the danger and indicated the methods of prevention, and even the law, by certain apologies for action, had taken cognisance of these matters; but until the public were educated to the danger and the possibility of escape, that desired safety would never be accomplished. Their main object there that day was to consider the effect of the flesh from tuberculous animals on the health of men.

He was sure that all who realised that there was such a danger would deem it a privilege to do his share in trying to avert it. It was, however, important that they be convinced of the danger, and, as far as possible, of its degree. They in Great Britain were not credited with being an impetuous people, their reason must be appealed to, but with solid basis of action, their sense of justice would rise to the occasion. It was under that conviction that he would venture to proceed to a cursory consideration of the subject, or, particularly, that part of it concerned with the flesh of tuberculous animals. The malady, which assumed various forms, and was known by many names, was invariably caused by the entrance into the body of a very minute germ or microbe, now almost familiarly known as the tubercle bacillus, and though certain states of the system and other circumstances might be essential to its growth, development, and power to produce the disease there, without the tubercle germ there could be no tuberculosis. That germ was always derived from some man or animal affected with the disease. The same germ produced tuberculosis in man and animals, and it might enter the body of either in the dust, in food and drink, and even through a wound in the skin. Though very many species of animals, including horses, cats, dogs, rabbits, &c., were liable, it was much more common in the domesticated animals whose flesh is used for food—among cattle and pigs. Of cattle by far the larger number of cases were found in dairy cows, especially the older ones. Indeed, the main factor in bringing about that incidence was the congregating for long periods indoors. Sheep which lead a life in the open air are very rarely affected. Cows in mild climates, such as Jersey where housing is little known, enjoy comparative, if not complete, freedom. In fact, overcrowding, with bad ventilation and lack of sunlight in man and animals, is accountable for the occurrence of a high percentage. But observation had over and over again proved that neither overcrowding, want of ventilation, nor general insanitary conditions alone induced tuberculosis. The tuberculous animal was the prime—the only—factor in providing the essential tubercle germ, and if we desire to prevent tuberculosis in cattle we must remove tuberculosis from healthy animals. According to a variety of circumstances associated with the mode of entry, the state of the constitution in general, or of certain parts of the body, the germ settled in some situation, and there it grew and induced the disease in the part. It became localised, and they might take it that at first tuberculosis was a "localised disease," and experience had told them that it usually remained so for a long time. The tubercle bacilli tended to remain in that part, and for some time other parts were free. In infection it might be, and commonly was, that the germ or germs settled only in one spot or resting-place, and that for a longer or shorter time only was "tuberculous." It might be that at that or a subsequent infection germs from without might have found several resting-places, and induced tuberculosis in several different parts of the body. The condition was, however, according to present interpretation, still "localised tuberculosis." While, however, the germs were active in any of these positions, they were more or less rapidly increasing in number, destroying the healthy structure of the part, and extending in that way so as to produce large tuberculous lesions, whence they might gain entrance to a vessel, and so get to the

heart, from which they were discharged into the blood stream, and, it was believed, sent over the system. When that was the case the so-called "generalised tuberculosis" existed, and it was usually regarded that under such conditions it was unsafe to say that any part of an animal was free from tubercle germs. More recent experiments, however, went to show that when such an occurrence took place the great majority of the bacilli were arrested in the lungs, through which all blood from the heart must pass. That produced in both the lungs innumerable small tubercles, the so-called "miliary tuberculosis." From that fact the lungs yielded the strongest and probably the only trustworthy evidence of "generalised tuberculosis." Absence of tuberculosis in the other organs of the body in the experiments referred to, at any rate forcibly suggested that even in the so-called "generalised tuberculosis" there was not a general distribution of the germs throughout the body of the animal. It might, however, not be inferred from this that tubercle germs might invade the body in no other way than by the blood stream. Their tendency was to spread by the lymphatics to the glands, and there, or on their way, they might be arrested and set up tuberculosis, and so contaminate many parts, some of which are removed easily, and others cannot be so removed. There was little tendency for the germ to rest and grow in the muscle or lean flesh, but the lesions might be so numerous and closely associated with the edible parts of the carcass that they could not be separated with certainty. That might apply to one lesion or many. When the lesion was in connection with the outer world, as sometimes happens when the lungs, udder, throat, intestines, &c., were their seats, the tubercle germs might be thrown off by the animal, and so become a danger to others. They were then capable of living outside the body for a long time, though they did not multiply there under ordinary circumstances, and be conveyed to healthy animals by dust or food. It was, however, well known that they were killed by subjection to high temperatures, and a very short exposure to a heat of 180 degrees F., i.e., 32 degrees under boiling point, destroyed them. The general effect of the tubercle germ on the constitution of the animal affected, apart from the destruction of the portion it invaded, was usually marvellously little. It was not uncommon to find the most extensive tuberculosis in cattle in prime condition and apparently perfect health. It would be thus seen that the flesh of animals might contain the germ, and as it was a truism "that any man or animal taking the tubercle bacillus into his system runs a risk of becoming tuberculous," there was a certain amount of danger associated with the consumption of flesh from tuberculous animals; a danger of which they urgently desire to form a just estimate. Though granting that the conservation of human health outweighed every other consideration, it need not obscure the fact that the prevalence of the disease in our herds of cattle, pigs, &c., caused an enormous drain on the resources of the stockowner. The most moderate computation indicated that between 20 and 30 per cent. of dairy cattle were affected, and in a lesser degree than young stock. The danger to the health of man through drinking milk, a real danger indeed, scarcely came within the scope of that lecture, but the stock-owner had every inducement to rid his herds of tuberculosis. In the natural order of things, however, sooner or later, this 20 or 30 per cent. of tuberculous cows, and the smaller proportion of other cattle and the pigs so affected which did not succumb, came to the butcher and the meat trade. It was that enormous impost which had to be faced, and considered by the conservators of public health and the vendors of meat. The prevalence of tuberculosis in cattle was brought to light in the slaughter of cattle for pleuropneumonia.

In 1888 a Departmental Committee sat, and going beyond the scope of their instruction, recommended that, owing to the danger to consumers of flesh, all carcasses in which existed a trace of tuberculosis should be confiscated and destroyed. The application of the tuberculin test yielded evidence of an even higher percentage

of tuberculous cattle, and with that evidence there was perhaps little wonder, that that portion of the medical world and the public, who interested themselves, should become excited, and that an idea should prevail and extend that tuberculosis in man was a cattle disease, communicated to him by eating meat and drinking milk, and that the responsibility for the human mortality rested with the Board of Agriculture. Owing to the want of system, uniformity and proper returns, the Commissioners were unable to form an opinion as to the financial results of the application of their proposed standard, so were compelled to have recourse to some returns for foreign countries. In Saxony, where the inspectors are all veterinary surgeons, and the inspection rigid and discriminating, tuberculosis was found to exist in 22,758 carcasses (being 27.48 per cent. of the whole numbers slaughtered). The whole of these, according to the practice of some authorities in this country, would have been confiscated and destroyed without compensation. In Saxony they were dealt with as follows:—Of the total number 22,758 showing tuberculous lesions, 21,062, or 92 per cent., were passed as fit for food; 1,256 carcasses, or 5½ per cent., were disposed of in the Freibank as inferior meat, at a fixed cheap rate; and the remainder, 440 carcasses, or 2 per cent. of the whole number pronounced tuberculous in a greater or less degree, were condemned as unfit for food and destroyed. The report of the chief sanitary inspector of London states that 30 per cent. of the cows which were examined under his authority contained tuberculous lesions, and he found that only 6 per cent. had to be condemned as unfit for human food. The other 24 per cent. the tuberculous lesions were removed and the flesh was allowed with safety to go into the market. He went on to advocate a system of public slaughter-houses and the marking of foreign meat. On the question of compensation to owners of condemned carcasses the Commission were unable to come to a unanimous conclusion, but he thought it probable that many present would endorse the views of the minority that the owner should receive compensation on certain conditions, and he did not think their demand would be regarded as extravagant by any who believed that the principles of compensation should be applied to tuberculosis. Though scientific investigation and common observation went to prove that the danger arising from eating the flesh of tuberculous animals was much over-estimated, no one could deny that the edible parts of tuberculous animals might contain the tubercle germs, rarely as this may be. No proof was required that inspection of meat was necessary, and, if necessary for large communities, it was necessary for the more scattered population. It should be uniform. It has been clearly shown to be wanton waste to destroy but a small portion of the flesh of most tuberculous animals. Indeed, it had been said there were grave doubts as to whether flesh cooked in the ordinary fashion ever induced tuberculosis in man. A greater danger was undoubtedly associated with milk from cows with tuberculous udders. Other countries, Belgium, Massachusetts, &c., have adopted extreme measures, probably without counting the cost or measuring the possibilities, and have had to withdraw. When it was for a moment considered that a large proportion of our six million cattle was tuberculous, that of our two and a half million cows probably more than 800,000 were affected in a lesser or greater degree, they should realise the enormity of such an undertaking. To withdraw all our milk cows reacting to tuberculin from our dairies would paralyse the dairy industry, arrest breeding, send the trade abroad, perhaps never to be recovered. And after such an attempt there were grave reasons for supposing that some tuberculosis would still exist, while the cost would be immense. He shared the opinion that the disease might be very materially reduced, if not eliminated, by rational precautionary measures. He was under the conviction that no Government would be cajoled into giving full compensation. In the meantime in the absence of compensation from the State, it appeared to him a system of mutual insurance should be adopted in which contributions should be made by the farmer who sells the tuberculous animal, by the

local authority representing the consumers' benefit in health, and by the butcher, who may or may not take the risk into consideration in his dealings, but whose burdens would be thereby lightened.

## Transactions of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD JULY 3RD, 1901.

PETER HORROCKS, M.D., President, in the Chair.

#### SPECIMENS.

##### MENSTRUAL MEMBRANE IN EXFOLIATIVE ENDOMETRITIS.

DR. CUTHBERT LOCKYER showed a specimen of a menstrual membrane passed by a single woman, *æt.* 19. Her periods had been normal till six months previously, when they began to be profuse, and shreds were passed; but the patient had no pain. After curetting, no more membranes were passed. He thought the condition was best described as exfoliative endometritis.

Remarks on the specimen were made by the President, Mr. Alban Doran, and Dr. Eden.

##### CYSTIC CORPUS LUTEUM.

DR. RICHARD ALCOCK (Goole) showed this specimen. The patient had had septic endometritis following labour, and for ten months afterwards suffered greatly from severe pain on the left side. Abdominal section was then performed, and the ovary of that side was removed. It contained a cyst the size of a plum, on puncturing which fluid escaped under considerable tension. It proved to be a cystic corpus luteum; in its collapsed state it surrounded a considerable portion of the ovary, the section suggesting one across the empty right ventricle. Dr. Alcock suggested that the septic endometritis after labour might have led to the corpus luteum becoming cystic, instead of undergoing its normal involution.

MR. ALBAN DORAN said that Dr. Alcock's explanation of the origin of this corpus luteum cyst was ingenious and interesting; it might quite well be the correct explanation. Certainly, suppurating cysts of the corpus luteum were known to result from septic perimetritis.

Remarks were also made by the President and Drs. Spencer and Eden.

##### CARCINOMA OF THE OVARY.

DR. FAIRBAIRN showed a specimen removed from a patient by Mr. Bland-Sutton. The pedicle was twisted. The contents of the cyst were soft, and somewhat suggested a dermoid; but microscopic examination showed that it was a case of carcinoma. An interesting point was that the tumour had a thick capsule, which was quite intact; the growth was therefore well circumscribed, and the prognosis was good. The patient had suffered from menorrhagia and metrorrhagia for some months.

DR. ARTHUR GILES said that the case possessed considerable clinical as well as pathological interest, especially from the point of view of diagnosis. He saw the patient in the out-patient department, and the history of hemorrhage going on for some months, without any very obvious cause, and of marked pain in the left side, together with the presence of a well-defined tumour to the side of the uterus, led him to diagnose extra-uterine gestation, and this was the view generally taken when she was in the hospital. An element of doubt in the diagnosis was introduced by the mobility of the tumour; he had, however, known exceptional cases, where the tumour in a case of extra-uterine gestation was mobile, even though of considerable size.

DR. CULLINGWORTH said, in reference to Dr. Giles's observations on diagnosis, that in his experience a considerable hemorrhage was not characteristic of ectopic gestation; the blood generally came away in a dribble, and was not arterial, but dark, and resembled menstrual blood. He had often found this distinction of service in arriving at a diagnosis.

Some observations were also made by the President, Mr. Alban Doran, Dr. Duncan, and Dr. Bonney.

## INCOMPLETE TUBAL ABORTION.

Dr. FAIRBAIRN also showed this specimen, removed by Dr. Cullingworth. It was a partial expulsion of a foetus, four inches long, through the fimbriated extremity of the Fallopian tube. The after-coming head of the foetus was retained within the tube.

Dr. HERMAN said that it was an interesting question what became of the tubal mole in the pre-operative days; no specimens found in museums dated back more than a recent period. He presumed that a mole left to nature became absorbed. He operated a few days ago on a patient, and removed a recent mole from one side; on the other side the tube was occluded, and adherent to bowel, and contained a gummy fluid. He believed that this represented an older mole that had become mainly absorbed.

Dr. WILLIAM DUNCAN agreed with Dr. Herman that a mole when left alone became absorbed. He operated recently for double hydrosalpinx on a patient whom he had seen eleven years before. She then had a tubal gestation which was not operated upon at the time. At the operation no trace was found of the former tubal pregnancy.

After some remarks by the President and Dr. Drummond Robinson, Dr. CULLINGWORTH gave a brief account of some clinical features in the case.

## CARCINOMA OF THE UTERUS SUBSEQUENT TO DOUBLE OVARICTOMY.

Mr. A. C. BUTLER-SMYTHE showed a uterus, the seat of carcinoma of the cervix and pyometra, removed from a patient who had had a double ovariectomy performed eighteen years previously; a large multi-locular cyst having been removed on one side, and a cystic ovary the size of a Tangerine orange on the other side.

Dr. HERMAN stated that he had had a case of carcinoma of the cervix occurring sixteen years after he had performed double oophorectomy.

Dr. HERBERT SPENCER mentioned that two other such cases had been recorded in the Society's Transactions.

Further observations were contributed by Mr. Alban Doran, Dr. Amand Routh, and Dr. W. Tate.

Dr. WILLIAM DUNCAN showed (1) a myoma with a large cystic cavity; (2) a myomatous uterus studded with a very large number of small fibroid nodules.

## SPONTANEOUS RUPTURE OF THE UTERUS IN PLACENTA PRÆVIA.

A paper on this subject was contributed by Dr. J. PRESTON MAXWELL, of China. It was the record of a case successfully treated by gauze-packing from the vagina.

Dr. F. H. CHAMPNEYS remarked that this was a valuable record of a rare occurrence, the small size of the child and the absence of causes for rupture being especially notable. He had no doubt that Dr. Maxwell had done the right thing; for in cases where the child had not got into the peritoneal cavity, gauze packing had been found to give the best results.

Dr. HERMAN believed that there was very little difference in the consistence of the uterus in cases of placenta prævia and in other cases; it had been said that a cause of "spontaneous" rupture of the uterus was fatty degeneration of its muscle fibres; but he did not believe that the existence of fatty degeneration of the uterus was established, or that it was a cause of rupture. Dr. Helme had shown that there was no fatty degeneration in the cases he examined; they were not, however, human uteri.

Dr. DRUMMOND ROBINSON said that he had had an opportunity of examining two human involuting uteri, and had found no fat at all.

Dr. HERBERT SPENCER said that he had examined several uteri where spontaneous rupture had occurred, and had found no fat. He was glad to find that Dr. Maxwell practised gauze packing, for his experience was entirely in favour of this mode of treatment, except in the cases mentioned by Dr. Champneys.

Dr. AMAND ROUTH had seen a case like the one recorded in the papers in the country; the woman, who was at the eighth month, had been in labour for a day or two and had had several hæmorrhages. He found a

placenta prævia and performed a podalic version. In the course of the night the foetus came through with a rush, and the uterus was torn through. Unfortunately, the patient died of septicæmia within a week. The cervix in this case did not appear to be specially thin, but rather presented the characters of a spasmodically contractile and undilatable cervix.

The discussion concluded with a few remarks by the President.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JULY 3RD.

Mr. A. G. MILLER, President, in the Chair.

Dr. SIMS WOODHEAD, in opening a discussion on

ALCOHOL IN ITS MEDICAL AND SCIENTIFIC ASPECTS, first alluded to the difficulty which existed in coming to any conclusion on the whole question of alcohol—a question which it was scarcely possible to approach without bias in one direction or another. We had to consider alcohol as a poison, as a drug, and as a food. It was, as all knew, a readily oxidisable substance, and was completely burned up in the body. Hence it was a producer of energy, and was therefore regarded by some as a food substance. The quantity of alcohol required to yield the requisite number of calories was, however, so great as to be a poisonous dose. It could not, therefore, be regarded as strictly comparable to other foods. It had been shown that the nutrient part of alcohol did not combine with the protoplasm of the cells of the body, as in the case of other foods, hence it differed totally from these in its properties. It was even doubtful whether it acted as a residuary food, and it seemed, like phosphorus, to have so powerful an affinity for oxygen that it diverted to its own use oxygen which would normally go to protect the body proteids from waste. In this respect it closely resembled the toxins of certain organisms, which have a similar attraction for oxygen. Its action, however, differs from that of the proteid toxins, because in process of time a certain amount of immunity is acquired against the latter, while the most prolonged action of alcohol produces not the least immunity, on account of the absence of any proteid reaction against it on the part of the cells. Alcohol was undoubtedly cumulative in its effects, and when circulating in the body along with another toxic agent, both their actions seemed to be intensified. This was seen in the case of arsenical neuritis following beer-drinking, and in other conditions. One of the most important effects of alcohol was undoubtedly in predisposing to the specific infectious diseases, and this had now been the subject of a great deal of experimental work by Abbott and others. It had been experimentally demonstrated that alcoholised rabbits were much more susceptible than normal to the poison of erysipelas, cholera, and anthrax. This had been confirmed as the result of observations made at Lille with the poisons of hydrophobia and tetanus, and it had, moreover, been proved that it was quite impossible to produce in an alcoholised rabbit any marked degree of immunity against the toxins of these diseases. As regards the virus of hydrophobia, the experience of the Pasteur Institute quite coincided with these experiments. In all these cases toxic doses of alcohol were employed, and objection might justly be taken to this, but a series of observations in Fraenkel's laboratory in Halle, in which the dosage of alcohol per kilo was less than that used systematically in the treatment of phthisis at Davos, had led to the same conclusions. The animals were much more susceptible to the toxins of diphtheria and tubercle, and, in particular, it was impossible to produce in them any high degree of immunity. These experiments were conducted with the greatest care, and he thought that we were not justified in disregarding their teaching simply because they had to do with the effects of alcohol. Its use in phthisis, especially, seemed questionable, both because immunisation of the patient—towards which all the efforts of the physician should be directed—was rendered more difficult of accomplishment, and the risk of

secondary infection consequently increased, and because it appeared irrational to administer a substance whose affinity for oxygen was so great in a disease where the respiratory capacity was already taxed to its utmost. Passing to the effect of alcohol on certain organs, Dr. Woodhead recalled his experience in the post-mortem room of myocarditis and fatty degeneration of the heart in cases of acute alcoholism. He also described recent observations which had been made on the changes in the nervous system caused by alcohol—changes exactly comparable to those resulting from the actions of other toxins—such as alterations in the staining of the Nissl's bodies, shrinkage of the dendrites, and the like, and said that if these were definitely proved they would constitute a great advance in our knowledge of the pathology of alcoholism. Another important action of alcohol was that on the thermogenetic centres. It was found, for instance, that while it was impossible by the application of external cold to reduce the temperature of a normal rabbit more than 3° C., yet if the animal were alcoholised the temperature could be reduced from 38.2° C. to 19.8° C.

Professor T. R. FRASER said that a large part of the difference of opinion as to the therapeutic value of alcohol, as well as to its dietetic position, turned on the question of dosage. Everyone knew that in large quantities, or in too frequent doses, alcohol was deleterious; but in small doses it had definite and valuable actions, in respect of which it could be replaced by no other drug. As regards its food value, it had been most conclusively proved that only the very smallest percentage was excreted, and that nearly all was burned up in the body. It was, therefore, impossible to doubt that it was an energy producer, and this very affinity for oxygen to which Professor Woodhead alluded as undesirable, was, in fact, one of its great advantages, because in the crisis of an acute illness, when ordinary food could not be absorbed, we could by the use of alcohol supply material from which energy sufficient to tide the patient over the period of greatest danger could be derived. In small doses its action upon the heart was of the very greatest value. It acted as a direct cardiac stimulant, which was easily and rapidly absorbed, quickening and strengthening the heart, and, most important of all, as the effect of the drug passed off the heart returned to its former state without the occurrence of any interval of depression. No other drug at our disposal had this action. Alcohol also dilated the blood vessels, and thereby flushed the tissues with blood and restored their vitality. Passing to its other uses, alcohol in small doses stimulates the flow of saliva without interfering with its digestive power, improves the appetite, increases the peptic secretion, and excites gastric peristalsis. It was therefore a stimulant to primary digestion, and in the widest sense of the word a true tonic remedy. As a producer of energy it had a nutritive value equivalent to that of fat. Its antipyretic action was well known and often extremely beneficial; it acted in this way by increasing the loss of heat, not by diminishing its production. In reference to what had been said as to its effect in increasing the susceptibility to specific infectious diseases, he thought that it must play an extremely unimportant part compared with other factors. In plague, for instance, the mortality among the Hindu population, which never touched alcohol, was almost 99 per cent., while among Europeans it was not more than 30 per cent.

Dr. CLOUSTON said that the place of alcohol as a cause of mental disease was undoubtedly extremely important. It was the most common factor noted in the admissions to the Edinburgh Royal Asylum—over 25 per cent. of all cases. But, after all, as a cause of insanity the neuropathic constitution was of infinitely greater consequence. In Dorsetshire, for instance, alcohol was given as a cause in only 5 per cent. of the admissions, though the proportion of insane persons to the total population was as high as in Edinburgh. The neuropathic brain, with its keen delight in art, poetry, and the gratification of the emotions, generally appeared to derive the supremest pleasure from the effects of alcohol. The action was really twofold, there being a diminution of inhibitory power and an increase in the more emotional or effective qualities of the brain. The frequency

of alcoholism in the neuropathic was, therefore, as much a consequence of the mental constitution as a cause of it. Experimental psychologists, by comparing the power of doing definite mental work—*e.g.*, arithmetical exercises and the like—before and after the ingestion of alcohol, had clearly proved that a lessened mental output was one of its effects. It was further shown that this action persists, and renders the effects of the second and succeeding doses of alcohol more easy of production. The speaker then referred to the desirability of a scientific commission being appointed to inquire into the whole question of alcohol. He also alluded to the very general desire on the part of the medical profession that the Legislature should assist them (as he believed could be done without undue interference with the liberty of the subject) in dealing with a class of patients who were unable to help in their own treatment.

Dr. AFFLECK spoke of the great responsibility which rested on the medical man who prescribed alcohol when it was not absolutely necessary. He thought it was often most difficult, especially for a young practitioner, to take up a definite stand. It was a drug which differed from all others, because patients often asked and expected the doctor to prescribe it. He used alcohol constantly in suitable cases, but his experience was leading him more and more to dispense with the very doses formerly used, in pneumonia, for example. As to what had been said in reference to its action in increasing the susceptibility to infectious diseases, one had only to look at pneumonia for an illustration of the fact. We all knew how grave was the prognosis in an alcoholic subject. The question was one in which he had always taken the very deepest interest, and he thought that it was futile to attempt to dissociate its medical and moral aspects.

Dr. JAMES RITCHIE alluded to insurance statistics as pointing to the evil effects of alcohol. From a large series of life-tables it was found that among the general assured the mortality was only 1½ per cent. below the expectation of life, while among teetotalers it was no less than 25 per cent. lower. Long clinical experience had convinced him that alcohol was most deleterious in many diseases. In gout he thought that medical men often shirked their duties in not enforcing total abstinence, and it was the same in some cases of chronic rheumatism. He had known many cases in which when alcohol was once absolutely stopped the gout had not again recurred. In heart disease, too, he thought that alcohol should seldom be given.

Dr. LESLIE MACKENZIE, speaking from the public health point of view, said that he could not believe that alcohol had any effect on the mortality from specific infectious diseases. In Leith there was an enormous amount of drunkenness—much more than in most other towns—yet it was notorious that its death-rate was much lower than that of any of the other large Scotch towns. Seeing that the main incidence of the ordinary infectious diseases was in children, who are naturally abstainers, he could not see that there was the slightest evidence that alcohol had any bearing on this question. The same applied to such infectious diseases as typhus, while in cholera we had a disease which occurred chiefly among an abstaining population. He then criticised adversely Dr. Arohdall Reid's theory of alcoholism, and asserted that there was no evidence of an inborn craving for the substance, or that it fills an organic want. Alcoholism was as much a consequence as a cause of poverty and vice, and formed only one part of the whole question which had to be dealt with by the social reformer rather than the sanitarian.

Dr. CHURCH thought that alcohol was of the very greatest value in acute diseases in children, but that it should be given with the finger on the pulse. If it reduced the pulse-rate and the temperature it was doing good, if not, harm.

Dr. P. A. YOUNG pointed out the enormous difference between the mortality and the morbidity of the two great friendly societies—the Rechabites and the Foresters—drawn from exactly the same class of the community, and differing only in their habits as to alcohol. The death-rate among the Foresters corresponded fairly closely with that of the general insur-

ance tables. He wished to point out that insurance companies did not accept lives in which there was a suspicion of intemperance, so that their tables of mortality gave the death-rate of moderate drinkers only, excluding those who excessed.

Dr. WELSH spoke of the diminished output of mental work following small doses of alcohol, and of its great value in certain forms of insomnia in the aged.

Dr. KEE (Superintendent of the City Hospital) said that he would not like to treat diphtheria without alcohol. Not all typhoid patients, by any means, required stimulants, but in diphtheria they were needed almost as a routine. Whenever he tried to lessen the amount of alcohol used in the diphtheria wards the percentage of cases of heart failure at once went up. The last three cases of fatal syncope in the hospital had been in patients who had seemed so slightly ill at the time of admission that stimulants were not ordered. If he was not to give alcohol, what drug was he to use? While he was waiting for strychnine or digitalis to act, the patient would be dead. In scarlet fever, alcohol was seldom needed; in typhoid and typhus he was guided by Jenner's axiom, "When in doubt, in typhus, stimulate; in typhoid, do not."

Professor Fraser and Dr. Woodhead shortly replied to the discussion.

#### PULMONARY AFFECTIONS.

At the Académie de Médecine M. Rendu read a paper on "Certain Pulmonary Affections Provoked by Lesions of the Nose, Ears or Pharynx." The pus from the above lesions created the pulmonary malady of which the pathogenic microbe was nothing less than that of the nasal or auricular suppuration. Frequently it was possible to trace from its origin the evolution of the malady: coryza, tonsillitis, pharyngitis, tracheitis, and finally bronchitis. The descending infection assumed varied forms, from an irritating cough to symptoms of pulmonary congestion, pneumonia, and broncho-pneumonia. Although the clinical phenomena were not exactly those of tuberculosis, confusion was not difficult; the diagnosis reposed on the presence of two facts; in the first place the existence of suppuration in the nose, ear, or frontal sinuses was noted, and generally when the patient was examined through the mouth a purulent stream was observed running down the pharynx. Secondly, the culture of that secretion and that of the bronchial expectoration furnished the same microbe, which was never that of tuberculosis. The lateral decubitus appeared to be favourable to the extension of the infection as the lung affected corresponded frequently to the side on which the patient had the habit of lying.

#### DEATH IN TYPHOID FEVER.

M. Ch. Fiessinger spoke on the cause of death in typhoid fever, and said that a fatal termination frequently occurred where the patients had not been treated by cold water. He employs either baths or the wet sheet. The baths are given at 72° F. every three hours as long as the fever attains or exceeds 102° F., and last from ten minutes to a quarter of an hour. Where the latter is not possible he employs the wet sheet. At 102° he prescribes the wet sheet spread on a blanket and wrapped around the patient for five minutes. At 103° the wrapping is repeated once again immediately, while at 104° the wet sheet is renewed three times.

The four complications which frequently cause death are intestinal hæmorrhage, perforation, cardio-pulmonary affections, and æsthenia. Frequently up to the twelfth or fifteenth day the patient is going on well, the treatment of laxatives, quinine, abundant drinks, and acidulated lotions seems to have been sufficient for a happy issue, when suddenly the fever attains 104° in the morning, the pulse becomes rapid and weak, the abdomen gets enlarged, the lungs become congested, the intellect obscured, speech difficult and indistinct, incontinence or retention of urine appears, death is at hand.

The benign form of the malady gave reason to hope that refrigeration could be dispensed with, and now it is almost too late to think of it. Let us try it, however, We need not expect anything much from other medication; injections of caffeine, camphorated oil, artificial serum, retard sometimes the fatal moment, but they hardly ever prevent it. The physician is discouraged; morning, noon, and night he injects fifteen or sixteen ounces of serum; twice or three times daily camphorated oil or caffeine, but without result; the patient sinks gradually. The only rational treatment is that of cold water, which is superior to all drugs, as it is the best agent against the typhoid poison. The wet sheet is more suitable when the fever exceeds 104°, and the prostration is great. In concluding, the speaker said that leaving out perforation, for which nothing could be done, the three other complications already mentioned could be avoided frequently by balsamation or the wet sheet. In the case of hæmorrhage, however, the cold bathing should be suspended three or four days as well as the enemata, and the accident treated with ice to the abdomen, injections of serum and the drugs usual in such cases.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 6th, 1901.

THE *Deutsch. Med. Zeitung*, No. 50, has an article by Dr. A. Tausig on

#### TANNIGEN.

He has used it for all forms of diarrhoea, not only in children but in adults. It does not diminish the appetite, and even when used for a lengthened period it was well borne. It was specially useful in the diarrhoea of children, even in those at the breast. In diarrhoea, with an alkaline reaction, tannigen especially proved its usefulness.

The best results were obtained in sub-acute and chronic diarrhoeas of children. After the third or fourth dose even, the mucus and water in the stools diminished, and generally after three or four days the stools appeared normal.

In chronic intestinal catarrh the course was rather slower, but the effect of the drug was unmistakable. He recommends the continuance of the drug in smaller doses, even after the diarrhoea has subsided. The dose given was, in children under two, 0.25 grms.; above that age, 0.5 grms., and four or five doses daily. If it could not be given in the ordinary ways, tabloid, powder, &c., it was given in gruel. The stools were often dark coloured from its use. In acute intestinal catarrh it was not so useful so long as the acute stage lasted.

Calomel and the other older and tried remedies were best then, and later, when the stools took on the catarrhal character, tannigen soon brought about an improvement.

Simple dyspepsia and isolated stomach affections did not appear suitable for tannigen treatment.

In diarrhoea from various causes, in connection with a slight chill, measles, excitement in nervously disposed persons, in irritable bowel (nervous weakness) it always acted favourably. In diarrhoea with vomiting it almost always had a good effect. In tuberculosis of the intestines, on the other hand, any good result was only transient.

At the Society for Innere Medizin, M. Wolff showed a series of preparations of

TUBERCULOUS ANIMALS AFTER TREATMENT BY HETOL AND IGAZOL.

Both remedies named had been recommended and highly lauded as being capable of building a wall of connective tissue around tuberculous patches, and thereby bringing the disease to a standstill. The animals shown were treated simultaneously, or almost so, by inoculation of tubercle and one of the substances named. The first animal shown was a rabbit that after infection with tubercle had twenty-three injections of hetol given in the space of three months. There was still some caseation at the margin of the cornea, and the disease had also spread to the lung. Four animals were shown of the first series, and in not one had the disease been checked in the least, in fact, the animals behaved just as the control animals did that got no hetol.

Experiments on the peritoneum showed a like state of things.

Three guinea pigs inhaled tuberculous dust and became infected, two were treated with hetol and the other without. One preparation showed the lungs thickly strewn with miliary tubercle and large caseous patches. Around the patches was a distinct wall of connective tissue, but the wall in the animal not treated by hetol was quite as distinctly marked. In the third animal there was also miliary tuberculosis and extension of the disease of the liver. The disease was no worse in the control animal. He had also used it in forty-two cases of phthisis injecting it into the gluteal region. The cases were selected as being slight and free from fever. The result was very unsatisfactory, no recovery took place, the râles remained unchanged.

As regarded igazol, which was given as recommended by Cervello of Palermo, by inhalation, the result was no better. The control animal lived the longer and showed the less advanced disease than the one treated by igazol. In fact, all the igazol animals died before the control ones. In three of the animals treated by igazol, again, pneumonia was set up. It was given prophylactically to thirteen men and six women, the inhalation lasting from three to four hours daily. Of the men nine remained in the same state, three got worse, and one died. The women almost all got worse. The igazol instead of having a curative effect had rather its opposite. The speakers who took part in the discussion, among whom were v. Leyden, A. Fraenkel, and Furbinger, complimented the speaker on his experiments and acknowledged that they tallied with their own clinical observations.

Hr. v. Leyden then showed a

CASE OF RECOVERY FROM TETANUS.

The treatment consisted of serum injections. A special epoch dated from the discovery of antitoxin serum, but the results were not brilliant. The antitoxin was injected subcutaneously to neutralise the poison in the blood, but the hoped-for result did not follow, and it was then found that animals died even when the poison in the blood was neutralised. The toxin was therefore present in another part of the body, and that could only be the spinal column or the far motor ganglion cells. The spinal fluid attracted the toxin, and fluid withdrawn from a case of tetanus was able to infect mice. It was now attempted to bring the antitoxin direct into the central nervous system, and the serum was introduced below the dura of the skull. But the results were again unsatisfactory. Then Jacob evolved the idea of injecting it into the spinal canal, but experiments on animals showed nothing decisive. In a case two years ago such an injection had a good effect. Since then there had been nine cases—three recovered and six died. In the case shown the result was very satisfactory. The patient, a groom, æt. 22, was admitted on May 15th with distinct signs of tetanus. On the third day of the disease subdural injection was made of 5 ccm. of antitoxin, after 10 ccm. of spinal fluid had been drawn off. The injection was repeated three days later. The dose given now was smaller than before, Behring's original case was 2 grm. (1 grm. = 20 ccm.). The result was "éclatante." The patient's temperature fell in a few hours from 41 to 38.5, and the next day to 37.4. This effect could certainly be looked upon as life saving. Life had never before been saved when the temperature had reached 41 C. The second injection had scarcely any effect upon the temperature. The tetanic symptoms subsided slowly, but the patient was able to swallow. After such an experience this method of treatment ought to be always followed. The other and usual remedies were given when special symptoms called for them.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 6th, 1901.

CYLINDERURIA AND ALBUMINURIA.

KOBLEB reported some time ago that he found in the urine of patients suffering from constipation the renal elements (cylinderuria as well as albuminuria), which would continue for several days, and rapidly disappear on relieving the bowels.

To test the accuracy of this observation, Wallerstein commenced to experiment on dogs and other animals by producing constipation and closing the anal opening with similar results. After twenty-four hours' closure, in the case of the guinea-pig the examinations were carefully commenced, and on the following day distinct traces of albumen with casts. In the dogs there were no albumen, but the urine was loaded with renal casts.

On post-mortem examination of the kidneys, the microscope revealed pronounced fatty degeneration of the epithelium in the medullary substance of the organ.

BACILLI OF DYSENTERY AND DIARRHŒA.

Kruse has been devoting his attention to the bacilli of dysentery and diarrhoea with the result that he has never seen any good from serum in combating the disease

in man or animal. He confirms the number and character of bacilli present, but the sovereign remedy yet was hygienic surrounding and a heroic endeavour to reduce the flow of water into the alimentary canal. There was a sort of diarrhoea to be met with in lunatic asylums which was not to be confounded with the true septic condition, but which could not be far removed from the more virulent congener.

#### MALARIA.

Coenen has provided us with a short history of malaria as taught in Italy at the present time. In his report he commences with Virchow's discovery of pigmentary granules in the red blood corpuscles from the heart of a man who died of intermitting fever in 1848. Little was heard of the subject till Laveran discovered his parasites in 1880, which he named *Oscillaria malariae*. This idea was strongly opposed as being the true cause of malaria. In 1885 his observations were frequently confirmed. The observations of Marchiafava, Celli and Golgi all supported Laveran's theory that although the bodies were differently described by different observers it was the same in different stages of its life history.

It was left to Koch to determine that there were three different species of these parasites. 1. The quartan parasite or *plasmodium malariae*, which has a diminutive amoeboid appearance, thriving in the red blood corpuscle and destroying the pigment of the cell. After seventy-two hours the deposit is broken up into eight or twelve segments, or spores. 2. Tertian parasite or *plasmodium vivax*, requires about forty-eight hours for its development, and then it breaks up into fifteen or thirty spores, or segments. 3. The parasite of the *estivo autumnal fever*.

Manson's theory of the mosquito transmitting the poison has been confirmed by Bignami, while Battista has accused the *anopheles claviger* as the true porter.

#### NOBOSCOMIAL GANGRENE.

A literary fight has arisen between Brabec, in Maydl's clinic, and Matsenauer, of Neumann's clinic over a few particulars in nosocomial gangrene which Brabec claims to be original, while Matsenauer sets them aside as unimportant. Brabec has gone so far as to classify diphtheritic phagedænic sores on the anal and genital region as closely allied to hospital gangrene, which Matsenauer ridicules as nonsense, while Brabec insists on the correctness of his diagnosis from the confirmation rendered by bacteriological examinations.

#### THE MANAGEMENT OF CONSUMPTION HOSPITALS.

The following extracts from a letter addressed by Professor Moriz Benedikt, of the Vienna University, to Dr. Professor Allbutt, of Cambridge, and published in the last number of the *Wien. Med. Woch.*, will be read with interest in Great Britain. He says:—

"As the subject of tuberculosis will, doubtless, be taken up, after the Congress, by the English Government, and by Municipalities and philanthropists, on a grand scale, it will be very necessary to avoid serious blunders. Nowhere is philanthropy so wasteful as in England. For Heaven's sake do not build huge pretentious palaces and hospitals, like big barracks, which in time would become strongholds of *bacilli*. Every home for consumptives should be so planned that it can be demolished or burnt down without much trouble when it can no longer be kept free from infection. A hut

system is accordingly to be preferred, and the fittings must be so selected, as to material and form, that they can be effectively disinfected. The mistake generally made is to spend all the money in hand on building. One must not forget how much philanthropy has to do, in regard to tuberculosis, in looking after the family when the [bread-winner is in a home] for consumptives; and, when he leaves it, with reduced power of work and resistance, in seeing that he does not take refuge in the demon of alcohol, and ruin both himself and his family.

"Small colonies, in localities free from dust and wind, are preferable to large sanatoria. Less serious cases might, perhaps, be entrusted to families living in suitable spots, for payment, and under the superintendence of doctors, as the danger of infection from single patients is not considerable."

## The Operating Theatres.

### CANCER HOSPITAL.

ABDOMINAL HYSTERECTOMY. — MR. CHAS. RYALL operated on a woman, *æt.* 35, who had been admitted for menorrhagia. About six months before, the periods first became profuse, and had steadily got more so, now lasting ten to fourteen days, with the passage of large clots, this having adduced profound *anæmia* in the patient. There was no great pain, no marked loss of flesh, and no interference with micturition, but there was obstinate constipation. On examination a tumour of the uterus was found filling the pelvis and extending about two fingers' breadth above the pubes. The os uteri was patulous and the length of the fundus considerably increased. A soft myoma of the uterus was diagnosed, and as palliative measures had previously been tried without any relief hysterectomy was recommended. Under ether a medium incision was made, and by the aid of a myoma screw the uterus with the tumour was drawn out of the wound; the vessels of the broad ligaments were temporarily secured with forceps, and the uterus was amputated about the level of the internal os, the vessels of the broad ligament were now permanently secured with silky ligatures, and the peritoneum was sewn over the cervical stump. The abdominal wall was closed in three layers. Mr. Ryall said that the tumour consisted of a soft single myoma growing from the posterior wall of the uterus, externally it was covered by peritoneum and internally by the endometrium. This type of tumours, he pointed out, was of a much more serious nature than the hard multiple fibroid, as it usually tends to gradually increase in size and was also associated with profuse menorrhagia which, after a time, might even threaten the patient's life, therefore he considered it was one of those cases where the surgeon had little hesitation in operating. Of all fibroid tumours he thought it was the one in which surgical treatment was most indicated. He also added that no new method was adopted in the technique of the operation. These kind of cases, he said, generally do very well. Occasionally, however, patients have afterwards a persistent vaginal discharge, owing to infection of the ligatures; the discharge finding its way through the cervical canal; this discharge, however, will cease when the offending ligature comes away, or is removed per vaginam. This *contretemps* (the vaginal discharge), he remarked, only occurred in a very small percentage of cases.

WEDNESDAY, JULY 10, 1901.

**THE HEAT WAVE IN NEW YORK.**

FROM America, a country that deals habitually in large figures, has recently come the news of a vast calamity that has swept the country in the shape of a heat wave. New York has been devastated by the advent of this unwelcome climatic scourge, and for a week or more has been paying on that score a death-toll to the extent of hundreds of dead and disabled in a single day. The official report for July 4th showed 190 deaths and 300 cases of prostration from heat, a number which we are assured is small when compared with the returns of the preceding day. Nor is the immediate outlook reassuring, for the Government weather expert says that although there has been a slight remission there are as yet no signs of permanent improvement. The area involved appears to comprise more or less completely the northern States east of the Rocky Mountains. Naturally the occurrence of so great a disaster in America is calculated to cause some uneasiness in Transatlantic countries, inasmuch as it has long been recognised that some of them, notably the United Kingdom, have in many if not most cases an unwelcome reversion of the meteorological extremes experienced in the United States. For a long time past British Army surgeons have been familiar with the disease among our troops serving in tropical and sub-tropical climates. Curiously enough, in spite of the great strides of scientific medicine, especially in the field of tropical diseases, the ætiology of "sunstroke" still remains obscure. Excluding the apyretic cases, the name of "thermic fever," or "siriassis," is usually applied to the far commoner form, in which an early symptom is a sudden rise of temperature which mounts to 105° F., 110° F., or even higher. The more marked features of the attack are headache, loss of consciousness, vomiting, and shock, and ending either in death from asphyxia or heart failure, or

in recovery with tendency to relapse and many sequela. The theory of causation hitherto most commonly accepted has been the somewhat vague statement that the extreme heat has disturbed the temperature-controlling centres in the brain and the spinal cord. The pyrexial cases, however, have lately been regarded by some observers as due to specific invasion, upon such grounds as their suddenness of onset, their marked peculiarities of type, and the tolerance or immunity as regards them found among natives and old residents. So eminent an authority as Dr. Sambon does not hesitate to include thermic fever among the infectious fevers. He has pointed out that the distribution of the malady is practically restricted to low-lying districts, and that it is never met with much above an altitude of 600 feet. This standpoint boldly places siriassis among endemic diseases; and extreme solar heat must according to that view be considered as a necessary concomitant in its production. In other words, while heat is a necessary contributory factor the actual source of the malady must be sought in other directions. It will undoubtedly occur to many of our readers with regard to Dr. Sambon's observations that New York is built on low-lying, swampy ground. Fortunately, while the exact pathology of heat apoplexy is still uncertain, a considerable advance has, nevertheless, been made in practical treatment of the condition. One of the most powerful remedies is cold, applied in various forms, together with prompt and continued stimulation in order to combat the ever present danger of heart failure. Under the best methods, however, the case mortality among British troops in India is stated by Dr. Manton to be one in four. By way of prevention it is important to adopt light clothing, to avoid alcohol, to refrain as far as may be from any mental or bodily strain, to live simply, and to keep out of the sun as far as possible. Meanwhile, it is earnestly to be hoped that the heat wave will not reach our shores.

**THE SURGERY OF UTERINE PROLAPSE.**

ONE of the first problems to attract the attention of the new school of gynecologists was the means of affording permanent relief to that distressing condition, prolapse of the uterus. The etiology of this affection is not as clear as one could wish. It is ascribed to stretching or relaxation (?) of the ligaments supporting the uterus from above and, incidentally, to rupture of the perineum, although the latter lesion cannot play a very important part in its production, seeing that a remedial operation for the latter does not necessarily effect a cure of the former. It is said to occur in women of lax fibre, but this is a vague expression which does not convey any very definite idea. Clinically, however, prolapse of the uterus is very frequently met with, and is productive of considerable discomfort even in the mild form in which the organ does not pass beyond the vulva. In its severer forms it is an evil not to be borne, and it

seriously handicaps women who are dependent upon their exertions for a living, or who have household duties to perform. It is of course only in the severer forms that surgical intervention is likely to commend itself for adoption. The lesser degrees can usually be kept within reasonable limits, at any rate for a time, by means of a suitable pessary, although we have to consider not only the discomfort which the wearing of a pessary sufficiently large to keep in place entails, but also the fact that sooner or later the dilating pressure which it exerts on the walls of the vagina reduces its supporting powers. In devising a means of affording efficient support to the uterus, we have to bear in mind that we are not dealing with an organ like the kidney which is always, roughly speaking, of the same size. We have to allow for pregnancy, and moreover care must be taken not to leave the parts in a state which might favour strangulation. Of course all suspensions of the uterus of whatever kind are to some extent mere makeshifts, but anchorage of the organ by means of the round ligaments is the nearest approach to the ideal, and as a choice between evils the round ligament suspension is superior to all others both from a physiological and from a practical point of view. The operation devised by Alexander and modified by Kellog is perhaps the most useful, though it is sharply criticised on both sides of the Atlantic. It is a somewhat difficult operation requiring, like most of the abdominal operations, skill and training for its successful execution, but the principal drawback seems to be the difficulty of finding the ligaments. The Kelly operation, it is urged, often leads to serious embarrassment in pregnancy and may even offer insuperable obstacles to parturition, so that it is only suitable as a post-climacteric operation, or in the case of women who have been rendered sterile by removal of the uterine appendages. At present we have virtually no choice between these operations and leaving matters much as they are. What surgeons must aim at is an operation which will utilise the natural supports of the uterus, will ensure a certain amount of mobility, will adapt itself to the functions of the uterus, will be lasting in its results, and will be reasonably easy of execution. Various operations have been proposed, for which it is claimed that they fulfil these desiderata, but the results obtained by surgeons who follow the directions of the inventor do not tally with those on which the claim is based, so that we may take it there is still room for further modifications in the technique of this operation before it can be confidently recommended for general adoption.

#### RAILWAY HYGIENE.

THE number of railway passengers has increased from 73,000,000 in 1850 to 1,107,000,000 in 1900. Until a few years ago the different railway companies seemed quite indifferent to the hygienic condition of the vehicles they provided for the public. In some few instances passengers who suffered from the effects of long retention of urine and so forth obtained good

damages, and it was found to be in the interests of the shareholders to provide proper lavatory accommodation. Competition was also a factor in producing more roomy carriages, better ventilation, an improved system of warming the coaches, and seats framed more for comfort than torture, which seemed the former rule. Thus the more glaring defects were got rid of, and it became possible to travel third-class in comparative comfort. But even now railway travelling implies many risks from the unhygienic conditions of many of the carriages of every class. The loathsome and dangerous habit of spitting on the floor of carriages is still practised, and in the evening of the day many third-class carriages become filthy from the habit. There is no systematic cleansing of the floor of such carriages on the completion of each journey as there should be. If the habit of spitting in trains cannot be put down suitable spittoons should be provided. We think that in all trains a special carriage should be provided for invalids; at present the wealthy invalid traveller may experience little inconvenience on his journey, but it should be possible for the man of limited means to secure a couch, or bed, and some little extra attention on his journey. Railways are our common means of transit, the great powers conferred on the companies have practically placed the travelling public at their mercy, and companies ought to remember that they have their duties as well as their rights. But over and above all these details reform is required, especially in saloon and first-class carriages, of which the thick carpets, brushed daily, impregnate the cloth-covered cushions, the depressions made by the buttons, the crevices between the seat cushion and the back cushion with all manner of foulness carried on the feet of travellers from the streets and platforms. A quick, sharp brush, which is all they get from the whisk of the railway porter, simply displaces a little cloud of dust from one corner to another. There should be no fixed cushions or nailed-on covers in railway carriages—regard for public health forbids it. All the furniture and fittings of a railway carriage should be removed at the end of each journey and disinfected and the carriage thoroughly cleansed before being sent on another journey. Objection may be taken to the cost of such measures for preserving the health of the travelling public; but we think that they are fully justified by the fact that many millions of the public make use of the railway, and their lives are quite as precious as those of oxen, and we need not remind our readers that after every journey a cattle waggon must be cleansed and thoroughly disinfected.

#### Notes on Current Topics.

##### The National Hospital for the Paralysed and Epileptic.

THE report of the Committee of Inquiry appointed to investigate the affairs of the National Hospital for the Paralysed and Epileptic was adopted by the

governors and subscribers of that institution on Saturday last. The effect of this is to put two members of the medical staff on the Board of Management, to abolish the office of Secretary-Director, and to provide for the revision of the rules. During the course of this controversy, we have from time to time warned the Board of Management what the result must be of treating eminent medical men on their staff "as if they were porters," a term, it will be remembered, actually applied to the members of their medical staff by that body. The Board have received their just punishment in the report of the Committee of Inquiry, and to resign appears to be the only dignified course left to them to pursue. In addition to having to listen to some stinging remarks from Mr. Melvill Green, the Board received a most severe and just rebuke from the medical staff, for which they had only themselves to thank. The chairman actually declared that the medical staff had never informed the Board of the more serious defects dealt with in the report, a particularly foolish statement to advance, because the report actually blames the Board for intimating to the medical staff that they were not to report defects to them, but to the Secretary-Director, and to him only. The spokesman of the medical staff in this matter was Mr. Horsley, and all that the Chairman of the Board could find to say in mitigation, after having to submit to the justly severe censure administered, was a meek appeal that he hoped he would not be thought to have been disingenuous. A strong committee has been formed to reorganise the hospital, and with a prospect of proper government an even larger measure of success than it has already secured can be confidently anticipated for this excellent charity.

#### Cæsarean Section.

THE advance of medical science has enabled the practitioner of to-day to discuss with no uncertain mind the propriety and safety of delivering by Cæsarean section a woman at term who wishes for a living child, but on whom the induction of early labour at the proper time has not for some reason been practised, and in whom the pelvis is too small to allow a living child to pass at term. It is certainly a sign of the modern trend of thought that Professor Sinclair, of Manchester, should have chosen the present time for delivering "A Plea for Cæsarean Section" at the London Polyclinic, on June 26th. Very notable attention was paid by the audience to the lecturer's description of his last case of Cæsarean section, which, he stated, was the first operation of the kind that had been done without a general anæsthetic since the introduction of chloroform, local anæsthesia being procured by the injection of solution of cocaine. It took only five minutes for the patient to become absolutely anæsthetised from the waist downwards. She was blindfolded and cotton-wool put into her ears so as to avoid anything being seen or heard by her to

cause shock, and a nurse stood by her side to comfort her during the progress of the operation. The patient complained of no pain and simply asked for a drink. The reason for employing cocaine in this case was because the patient had a dilated heart, and had been the subject of bronchitis for many winters previously. It is possible that the place of chloroform may be taken by this method of injecting cocaine to secure local anæsthesia, and this particular woman, whose case was commented on by Professor Sinclair, did very well and made an excellent recovery despite the fact that she was a somewhat elderly primipara, aged 39. It must be admitted that one of the causes of fatal endings in the operation for Cæsarean section is the injudicious interference previous to the operation, and also, to quote Professor Sinclair again, the want of a fixed resolution as to a definite and distinct line of action and early diagnosis of the condition. After this early diagnosis there should be prompt and decided action. The most hazardous course that can be followed in these cases is to finally resort to Cæsarean section after futile delay and objectless shilly-shallying, taking up one plan only to give it up for another, and generally exhausting the vitality of the patient.

#### The Midwives Bill.

By the permission of the Lady Balfour of Burleigh, the Association for Promoting Compulsory Registration of Midwives held a meeting in her drawing room at 47, Cadogan Square, on June 28th, to receive the annual report and to generally help forward the Bill that the Association so nearly managed to pass through the House of Commons. Lord Balfour of Burleigh comforted the members for the disappointment in the failure of the Bill to get through by assuring them of his warm sympathy with their efforts, and this friendly disposition on the part of a member of the Government was, as Mr. Crombie, M.P., pointed out, a matter for sincere congratulation from the point of view of the members of the Association. Members are to be induced to ballot for the Bill next Session, and the Government is to be shown that legislation must be obtained by means of private members and their constituents being persuaded to show great determination in pushing the Bill. Working-class mothers are to be addressed all over the country warning them of the risks they run in employing ignorant midwives. The support of the mothers is to be enlisted, and especially that of their husbands, who can vote, as the people most vitally concerned in the movement of the Association. The whole country is to be mapped out, and societies formed to appeal directly to the people and to rouse that public opinion without which Parliament will not move. A plea not unusual under similar circumstances is made for money, and the Association trusts that there will be no falling off in the donations. Great hopefulness was evidently aroused by the statement in the report that in the

opinion of Dr. Percy Boulton and Dr. Champneys medical opposition to the Midwives' Bill is largely diminishing. The Association consider that steady progress has been made in spreading a knowledge for the need of the legislation they propose, and that every year shows a more widespread conviction among the public that the present state of things cannot be allowed to continue.

#### Spinal Anæsthesia by Cataphoresis.

THE risk attendant on opening the dura mater of the spinal cord has, perhaps more than anything else, done much to make unpopular anæsthesia by the ordinary method of injecting the cord with cocaine. Injection of the fluid between the arachnoid membrane and the dura mater has, as has been noted in THE MEDICAL PRESS AND CIRCULAR, been recommended and tried, but it requires great dexterity to just penetrate the dura mater only, and there is always the doubt as to the success of the operation. To avoid the risk of the earlier operation and to get rid of all doubts as to the successful performance of the second, Dr. Leonard Corwing has proposed that cataphoresis be utilised to make the anæsthetic penetrate the spinal membranes. The method has been successfully tested, by its author, on a patient in a New York hospital, who underwent an osteotomy of the foot. The anæsthesia was so long in coming on, full half-an-hour, that ether inhalation was resorted to, but scarcely were the preliminary steps of the operation taken than the house surgeon drew attention to the fact that the patient, now entirely conscious, for the ether inhalation had been discontinued, was suffering no pain. From then on there was no giving of ether whatever, the patient conversing with those about him quite contentedly, and without the least sign of discomfort, "although cutting, chiselling, sawing, and suturing were indulged in, according to the technical demands of the occasion." (*New York Med. Jour.*) The steps of the operation differ considerably from any of those formerly proposed, in that the author makes an incision between the spinous processes of the fourth and fifth lumbar vertebræ, a little to the right of the ligamentum interspinosum, thrusting the knife down to the ligamentum subflavum. This being done he penetrates the ligament with a fine telescopic-like tube, which fits accurately the outer tube which rests on the ligamentum subflavum. The fine inner tube projects half-a-centimetre beyond the outer tube, and is rounded at its extremity, and is deficient in the sharpness necessary to penetrate the dura mater. Having pierced the ligaments a syringe is attached to the smaller tube by means of a socket, and the anæsthetic fluid is injected in the dura mater. The syringe and the smaller tube are now removed, and the positive pole of a galvanic battery is secured to the outer tube, and the negative sponge of the battery is placed on the abdomen; and the current turned on until the milliamperemeter showed three-tenths of a milliamperemeter. Should any doubt arise as to the perforation

of the dura mater by the inner tube the piston of the hypodermic syringe can be withdrawn, and if no spinal fluid is found the membrane is intact.

#### Important Legal Decision on the Sale of Food.

THE very important issue raised in the case of Wallis against Russel, commonly known as the "Cork Crab Case," has been decided, on appeal, in the King's Bench Division, by the Lord Chief Baron and Mr. Justice Andrews. To the medical profession the decision is of much importance, as it is distinctly and rightly based on the *caveat emptor* principle; any other principle would wreck the beneficent design of all the recent legislation passed for the protection of the buyer of food. The plain intent of buying food is to prepare it for human use, and the essential condition of sale is that the food is fit for human use. It was argued that crabs were natural products, not manufactured ones, and that they were sold as such without warranty. But as the Lord Chief Baron pointed out that the Act applied to goods of a description which it was in the course of a seller's business to supply, and that liability was to attach to the dealer as such. The case is one of great simplicity although it raised such important legal issues. The plaintiff bought of the defendant, who is a fishmonger, some crabs which were dressed and eaten by his wife and family. During the night marked toxic symptoms in all who ate of them were found, and their lives were saved with much difficulty, convalescence being long and staggering. Toxic effects from shellfish are not unusual; they may result from idiosyncrasy, from improper feeding of the crustaceans, or from the natural process of decay in fish kept too long. In this case there was, however, no question as to the freshness of the crabs. Idiosyncrasy was not considered, so we may suppose that there was none; but remains the question as to the site of the fishing grounds for the crustaceans. If the fish fed in a sewage impregnated district we might reasonably conclude that others would have suffered similarly to the plaintiff and his family; but there is no such account. We are told nothing of how the fish were cooked, or what, if any, drink was taken with them. The case has, however, definitely settled an important legal point that affects every member of the community, by establishing a principle that, though it may at times press hardly on vendors, is a protection to the public and a safeguard to public health.

#### Plague and Small-pox in Glasgow.

THE annual Congress of the Sanitary Inspectors of Scotland at Glasgow has naturally given rise to retrospects of the plague and pestilence to which the ancient town has of late been subjected. Lord Provost Chisholm very naturally congratulated his townfolk on the way in which bubonic plague had been stamped out of their midst, and the disease prevented from extending to other parts of Scotland.

At the same time he was obliged to admit that there were many unsanitary areas in the city that formed fit nursing places for infectious disease. That fact was illustrated by the recent epidemic of small-pox that had swept over them, but now, happily, had been banished. The experiences of that outbreak had left him more than ever a firm believer in the virtues of vaccination, but the public must not be permitted to imagine that universal vaccination would be any excuse for lax sanitary administration. With regard to the recent critical experiences of Glasgow, it may, perhaps, be permitted to remark that a Corporation which has sent plague so promptly to the right-about should surely be able to deal effectually with the less deadly home infections, such as small-pox and scarlet fever. But how, above all things, can so enlightened and progressive a municipal government permit the Clyde to remain the most offensive ink-black river of foul pollution known to the civilised world? What has the Lord Provost to say upon that point?

#### Chorea and Rheumatism.

"CHOREA is rheumatism of the brain, and I feel as certain of that as I do of anything in medicine." These are the words used by Sir Dyce Duckworth in addressing his students at St. Bartholomew's Hospital a short time since, and in support of his view he was able to add that the recent researches of Drs. Poynton and Payne have rendered his conception as nearly certain and positive by way of demonstration as anything can well be. These two observers have succeeded in inducing chorea in the rabbit by the inoculation of the diplococci of rheumatism, and they have detected these diplococci in the endothelial cells and capillaries of the brain. They found them not only there, but dipping into the motor centres of the rabbit's brain. That is almost as complete and perfect a demonstration of the nature of the disease as could be wished for, but Sir Dyce Duckworth was singularly fortunate in being able to quote an extremely interesting case of fatal chorea in the human subject, in which Drs. Poynton and Payne discovered these rheumatic organisms in the mitral valve and also in the motor cortex of the brain. The very natural conclusion these gentlemen have drawn is that chorea is induced by the presence of these diplococci or of the toxins which they produce in the brain. It would be difficult to describe the modern view of the morbid anatomy of chorea more concisely and clearly than Sir Dyce Duckworth, who says that so far as it has been studied it shows nothing incompatible with the theory that it is an inflammatory process depending on microbic invasion, and the symptoms of the disease appear to indicate that the changes are caused by multiple local lesions due to the deposition of a particular form of disease rather than to any diffuse toxæmia. Believing that the determination of this process to the brain will only occur in persons particularly and specifically predisposed to brain weak-

ness, we naturally come to regard it as rheumatism localised in that organ.

#### Foreign Students in Germany.

NO better testimony could be forthcoming of the high esteem in which German methods of teaching are held by the world at large than the very large number of foreigners who avail themselves of the facilities provided by the various universities. Apart from the Russian students, who, for political reasons, prefer German schools to their own, close upon two thousand other students of all nationalities rub shoulders with the native students. In view of the fact that the foreign students pay for their education on the same footing as the native contingent, one would have thought that both professors and the general body of students would have been flattered and pleased at this evidence of popularity. Apparently this is not the case, for a movement of protest against the large admixture of foreign students has been inaugurated, on the ground that the native students are crowded out. This is a very good reason for requesting the authorities to provide additional accommodation, but certainly not for proposing the exclusion of foreigners. We should be sorry to see German universities follow the example of the French in placing obstacles in the way of foreigners desirous of availing themselves of their educational institutions. In years gone by it was the boast of the French school that it was the favourite resort of the studious youths from all parts of the world, a proud position which a narrow-minded protectionism has ruined, although to its popularity with foreigners the intellectual pre-eminence which France formerly occupied in Europe, and indeed in the world, was largely due. Let our German scholars remember that science knows no frontier, and that it is a privilege to be jealously safeguarded to be able to attract and retain the affection of the studiously inclined.

#### Velociphilia.

THE disease which a French author has described under the name velociphilia is not a new one, though it has of late assumed an epidemic form. It was a mild and comparatively inoffensive affection so long as it could only be indulged in by those who were willing to use their legs for the purpose of rapid progression. It occasionally assumed an acute form in equestrians who risked life and limb in their endeavour to outrun the hounds; but it was not until the advent of the modern bicycle that it attained such dimensions as to constitute a peril for the public and a source of evil for the victims. Within the last few years the perfection attained by the motor car has been the means of developing the malady in a form dangerous at once to the public and to its victims. In years to come it may be that our faculties of direction and our agility may adapt themselves to new and altered requirements, but at present the motor car is an unmitigated terror to those whose nerves are ever being agitated by the peremptory

hoot. It is idle to look to repressive penalties to stem the course of the epidemic. Under the empire of this emotional mania the otherwise sane man rushes headlong to his doom, oblivious alike of the risks which beset him as he careers along the dusty road at express train speed, and of the dangers which his rapid passage entails on other travellers. The only effectual safeguard would be to refuse the liberty of the streets and roads to all cars not provided with a permit of circulation, such permit only being accorded on its being shown that the mechanism does not admit of a speed greater than that allowed by the traffic regulations. We do not attach much importance to the proposal to make these cars carry numbers. Enveloped in a cloud of dust, the outraged pedestrian would not be in a favourable position to distinguish the number of his assailant, which, moreover, it would be easy enough to mask at critical moments.

#### The Royal College of Surgeons of England.

THE ballot for the election of three members of the Council of the Royal College of Surgeons of England took place on July 4th, with the following results:—Mr. Arthur William Mayo Robson, 332 votes; Mr. William Watson Cheyne, 302; Mr. Richard Clement Lucas, 259. Of the unsuccessful candidates, Mr. John Hammond Morgan obtained 236 votes; Mr. Charles William Mansell Moullin, 235; Mr. Henry Hugh Clutton, 145; Mr. John Bland-Sutton, 193; and Mr. Jordan Lloyd, 93. Seven hundred and fifty Fellows voted by paper and eighteen in person. Mr. Mayo Robson and Mr. Watson Cheyne were declared to have been duly re-elected, and Mr. R. C. Lucas duly elected.

#### Indian Army Medical Reform.

SOME of the service journals are turning their attention to defects in the Indian Medical Department. On the principle that coming events cast their shadows before them, it is to be hoped that these editorial straws point to the setting in of a strong reforming current in that direction. From a scientific point of view the present system may be regarded as absolutely throttling to all individuality and its resulting efficiency. The test of a man's opinion appears to be his status in the army, a sacrosanct qualification quite apart from such lay trivialities as his scientific attainments. If we judge the tree by its fruits then the army medical service in India stands self-condemned. After generations of official administration the death-rate from cholera and enteric fever remains very much as it was, notwithstanding the vast scientific advances that preventive medicine has made in dealing with these scourges of mankind. Surely any service with a real grip of the situation would have long ago placed its standing camps and barracks on a sound sanitary footing. So far from that the average view of the Indian Army surgeon upon sanitary matters appears to belong to a fossil and pre-scientific age. Even now the essentially water-borne nature of cholera and enteric fever is not generally

recognised, or, at any rate, if recognised, is not reduced to a practical sanitary basis. The death-roll from preventible diseases among British troops in India is a standing reproach to our medical administration in that Empire. It is a significant fact, moreover, that few, if any, of the great advances in tropical medicine have hailed from India, in spite of the enormously wide field thrown open to scientific investigation.

#### The Congress of Tuberculosis.

THE arrangements for the approaching Congress, which is to be opened by the Duke of Cambridge on the 22nd inst., are now virtually complete, and there is every reason to anticipate a successful meeting. There is a veritable plethora of contributions, many of which will necessarily have to be "taken as read" in order to leave time for the discussion on the more important. It is hardly to be expected that anything strikingly new will issue from the debates. The object of these congresses is to educate the profession and the public by generalising the knowledge we already possess in regard to the etiology and spread of this fell disease, more particularly from the preventive aspect. We have as yet only touched the fringe of the subject, and as legislation cannot usefully go in advance of public opinion, it is all important to seize every opportunity of familiarising the public with the steps that have been taken and suggested with this object in view. It will greatly facilitate matters if those who intend taking part in the Congress will lose no time in inscribing their names at the headquarters, 20, Hanover Square.

#### The Reform of the Army Medical Department.

THE latest information vouchsafed in regard to the Committee of Experts renders it more than ever necessary to suspend judgment. It appears from a reply by Mr. Brodrick, in parliament, that the Committee will not take evidence, and that its proceedings will be private, though it will (of course) be open to any member of the Committee to submit alternative proposals. The least reassuring item of the reply was that which dealt with the scope of the reference which, it seems, is not to be made public. For the present, therefore, we must await the result of the Committee's deliberations. Meanwhile the competitive examinations have been suspended owing, it is asserted, to the lack of candidates.

#### An Unregistered Resident Medical Officer.

AT an inquest held last week at the Clayton Hospital, at Wakefield, Mr. George Robert Butler, M.R.C.S., who is acting as locum tenens for the assistant house surgeon, was a witness, and it transpired that his name did not appear on the *Medical Register*. The omission was explained on the ground that the last issue of the *Register* had been "newly printed," which we take to mean that this gentleman had omitted to make known his change of address, his name having been deleted in consequence. In consequence of the more stringent rules which have

come into force with respect to identification, there was, he stated, difficulty in the way of his getting the omission remedied until such time as he could go to London for the purpose. The Coroner pointed out that the witness was liable to a penalty, which the latter denied. Technically the Coroner was probably in the right, and in any event we trust this case will impress upon all duly qualified practitioners the propriety of taking care that their registration does not lapse

#### Bathing Fatalities.

THE advent of the summer season has been ushered in with even more than the usual list of bathing fatalities. Of such accidents there can be no doubt that a great many are preventable, that is to say, they should not occur under conditions of ordinary prudence. The number of persons who are drowned every year because they cannot swim is simply appalling. With regard to swimming it need hardly be remarked that in addition to being a most desirable acquirement it is a delightful and health-giving exercise, which brings grace and vigour to the body. To swim, however, especially in rough water is an extremely athletic exercise, and cannot be undertaken lightly by any person who is not more or less in that state of bodily fitness known as "training." The majority of bathing accidents probably happen to those who overtax their muscular resources too suddenly and too severely directly they get down to the seaside. Another risk arises from too frequent bathing. Only a few days ago an inquest was held on an ex-champion diver and swimmer who had tempted fate by swimming in the Thames several times in a single day. The fact is that those who contemplate seaside or inland bathing would do well to consult their medical attendant beforehand upon the matter. Many a man and woman with weak heart and feeble circulation, or with flabby muscles would thereby be warned against incurring unnecessary dangers. This sort of warning cannot be picked up from books, but may always be obtained from the ripe treasury of sagacity that is gathered by the practitioner from the broad harvest fields of medical practice.

#### The Spinal Symptoms of Tea Intoxication.

THE injurious effects of excessive indulgence in tea on the digestion and on the nervous system are familiar to most practitioners in this country, where tea inebriety is probably more frequent than elsewhere. It is doubtful, indeed, whether practitioners generally recognise to the full what a potent agent for evil tea-drinking may prove, especially when, as is so often the case, it is associated with inadequate nutrition. At a recent meeting of the Neurological Society of Philadelphia, Dr. Alfred Gordon showed some patients who presented certain well-defined spinal symptoms dependent apparently upon chronic tea intoxication. From ten to fifteen cups of tea daily had determined unsteadiness of gait and easily induced motor fatigue. The knee jerks were increased, sensation was impaired in some regions and enhanced in others. The pupils were unequal and

there was nystagmus. It is open to question whether these spinal symptoms were due exclusively to the tea or to the ingestion of minute quantities of lead therewith, but the communication suggests a useful field for future study.

#### Degrees for London Diplomates.

THE diplomates of the London Royal Colleges are still restlessly agitating for facilities at the hands of the reconstituted University of London in the direction of obtaining a medical degree, but so far there is no sign that their not unreasonable demand is likely to meet with a favourable reception at the hands of the authorities. There is no obvious reason why special facilities should not be offered to diplomates willing to comply with reasonable requirements in order to acquire the coveted degree. In future, no doubt, most metropolitan students will take care, when they enter on the study of medicine, to keep in touch with the University; but this leaves a very deserving category of qualified men out in the cold. The best course for them to adopt would be to formulate a tangible proposal which could be urged on the attention of the Senate for approval. It is useless to cry in the wilderness, leaving it to others to state exactly what they want.

#### Buxton Spa.

THE historical virtues of Buxton water are historical. So long ago as the Roman era it was devoted to the uses of Æsculapius. Since then it has always been a resort for invalids, and numerous references are to be found from time to time in the pages of English history. There is no need to refer to the fact that the mineral springs which have made Buxton famous are chiefly chalybeate and calcareous, the latter both hot and cold. In addition to the waters, however, visitors have the benefit of a glorious mountain and moorland scenery, which of its kind is perhaps the most compact and beautiful in all England. Indeed, it would be hard to imagine a more complete and restful change for the jaded town dweller than the clear and bracing atmosphere of Buxton. During the last two generations great changes have been effected in the town, whereby it has become one of the most perfectly appointed of spas. The Devonshire family, who for centuries past have practically ruled the country round, have taken the lead in these improvements. One of their greatest public benefactions has been the Devonshire Hospital, which for forty-two years has fulfilled a career of unbroken usefulness and success. During that period no less than 82,000 gouty and rheumatic patients have passed under treatment, and of that number it is reported that no less than 74,000 have received lasting benefit. It would be superfluous to comment upon a record of that kind, which speaks for itself with absolute emphasis, and bears eloquent testimony to the causes that have given Buxton a foremost place among English spas.

### The Toxæmia of Burns.

In those cases where death has occurred from the effects of severe burns evidence is not unfrequently found, on post-mortem examination, of ulceration of the duodenum. The theory for some time was that this lesion might be due to capillary embolism consequent upon the presence of disintegrated blood in the vessels. In connection with this point there was read, at the Association of American Physicians, a suggestive contribution by Dr. McCrae, of Montreal, entitled "A Study of a Series of Cases of Burns," in which the author puts forward the theory that the mischief may be due to a toxæmia similar to that produced by bacteria. The pathological processes at any rate present a striking similarity to those met with in diseases characterised by the presence of toxins in the blood. The investigations of Bardeen were suggested by the similarity of the lesions found after burns and those accompanying diphtheria, in fact the changes in burns are more proliferative than degenerative. One view, probably the least open to objection, is that the toxin elaborated in a burn is due to the action of heat on the blood in the superficial capillaries. The subject is one which, of course, has received the closest attention of skilled observers, but so far without clearing up the pathology of this very curious and interesting lesion.

#### PERSONAL.

LIEUT.-COLONEL R. W. BARNES, Royal Army Medical Corps, retired, has been granted the local rank of Colonel whilst in charge of a General Hospital in South Africa.

DR. J. W. WASHBOURN, Assistant Physician to Guy's Hospital, who went to South Africa with the Imperial Yeomanry Hospital in February, 1900, has returned to London.

MR. J. H. LITTLEJOHN, who for nearly six years has been Medical Officer of Health for Scarborough, has been appointed to a similar position at Hampstead, Middlesex, at a commencing salary of £600 per annum.

THE Gold Medal of the Royal Navy Medical Service for the year has been awarded to Surgeon A. J. Wernet.

THE John Malet Purser Medal has been awarded to Mr. Reginald H. Lee by the Council of Dublin University Medical School.

DR. J. LOBBAIN SMITH has been appointed a member of the Commission "to inquire into the present condition of the higher, general, and technical education available in Ireland outside Trinity College, Dublin, and to report as to what reforms, if any, are necessary in order to render that education adequate to the needs of the Irish people."

DR. ROBERT W. DOYNE, of Connaught Square, W., and Oxford, had an unique experience a few days since. He found himself in a carriage on the 1.13 express from Oxford alone with a man, and on awakening from a doze he noticed blood on his fellow traveller's boots. On examining him more closely he saw that he had cut his throat and was covered with blood, facts to which he subsequently testified at the inquest.

### Edinburgh.

[FROM OUR OWN CORRESPONDENT.]

#### THE LATE PROFESSOR TAIT.

PETER GUTHRIE TAIT, D.Sc., F.R.S Ed., &c., the celebrated exponent of natural philosophy in the University of Edinburgh, the one time Senior Wrangler of Cambridge, and prizeman in several other cognate matters at or about the same time, the collaborator with Lord Kelvin in various standard works on physics, died last week at the residence of his old friend and scientific colleague, Sir John Murray, in the suburb of Edinburgh known as Trinity, which lies by the sea-shore. A worthy successor to Hamilton and other celebrated occupants of the Edinburgh Chair of Natural Philosophy; a man of unusual mathematical talent, to whom intricate physical problems, comprehensible by but few others, were a joy, a pleasant amusement; a man wholly devoted to his life's work, to the exclusion of almost all else; he, nevertheless, possessed the gift of lucid explanation, the rare endowment of perfect adaptation in word and line of thought to the capacity of his hearers, and, another characteristic, by no means common, the possession of a fund of dry Caledonian humour.

Disdaining to be the slave of sartorial fashions, seldom seen in other than a grey tweed suit of a very personal cut, and a soft hat, he was in private the most genial and, at the same time the most rationally unconventional of men; one of the most interesting of conversationalists, ever disclosing, directly or indirectly, the fact that the working of his mind was chiefly influenced by his predominant characteristic—arithmetical and propositional.

Although he was not actually a member of the medical profession, he was directly associated with medicine in connection with the teaching of physics to medical students in their first year.

The conjoint works of Professor Tait and Lord Kelvin illustrate in a marked manner the extraordinary power of invention and theory of the latter; the striking faculty of the former for practical exposition and lucid description.

Tait, now and then, strayed from the strait and narrow path of higher mathematics; he investigated the flight of golf-balls, drew up formulæ to represent the characteristic course traversed by a child's indiarubber balloon when propelled through the air by a sharp blow.

For many years Professor Tait had filled the post of Secretary to the Royal Society of Edinburgh. Indeed, his devotion to this Society was almost Quixotic, as for its sake he resolutely declined to seek the higher honour of F.R.S.

Professor Tait's illness began last year, shortly after the death of his son, Lieutenant Freddie Tait—as well known for his physical achievements in golf as his father for his philosophical achievements in physics—killed in South Africa; caused him to resign all official posts some months ago, and at a time when a greater hope that his life, with that power of adding to the world's store of knowledge, the perquisite of his brain alone, might be prolonged to man's advantage, the sudden onset of hæmorrhage—the source of which has not as yet been indicated, although maybe aneurysmal—rapidly closed a life of unbroken application and of unquestionable benefit to mankind.

### Glasgow.

[FROM OUR OWN CORRESPONDENT.]

ROYAL INFIRMARY RECONSTRUCTION SCHEME.—This subject is exciting considerable attention in Glasgow, and calling forth much adverse criticism. Following the letter of Dr. R. Anderson, architect, to the newspapers, complaining of the shabby way he had been treated as assessor by the Committee in charge of the above scheme, in ignoring entirely the plans he had recommended for their consideration or acceptance, a further strong protest has been published in the news-

papers by the Glasgow Institute of Architects against the somewhat arbitrary and apparently unfair way in which the Committee has proceeded with the important work they have on hand. They state that the plans adopted by the Committee, which were not in any way recognised by the assessor, "are in many vital particulars inadequate and out of date," and that if the reconstruction is proceeded with according to those plans "the infirmary will not conform to the most modern standards of design in this class of building." We understand the plans adopted, without entering into any detail with reference to internal arrangements, will form a magnificent pile of buildings, calculated, unfortunately, from the high altitude of the memorial front (which is likely to prove a very late Jubilee memorial, by the way, of our late Queen) with its spire, to dwarf considerably the cathedral which is immediately adjacent. We are informed that Dr. E. Anderson's reports were somewhat meagre, and that while he recommended several plans, to the entire exclusion of those selected by the Committee, he unfortunately did not enter into detail, giving his reasons for the awards he made to the exclusion of others. The matter has assumed somewhat serious dimensions, as the Institute of Architects is not satisfied with the explanation given by the managers and the Executive in the official statement issued to the public. The Institute suggests that the plans should be submitted to one or more independent hospital authorities of recognised and outstanding position for consideration and report, and further makes the fair proposal that should their contention not be borne out by the report received, they would meet the cost if the Executive object to the outlay involved, while submitting before hand the name or names of the experts proposed on obtaining the necessary facilities from the Committee. As there is considerable diversity of opinion with regard to the plans adopted, and from the firm attitude of such an influential body as the Institute of Architects in the matter, it behoves the Executive to give the subject very serious and thoughtful consideration. They have charge of an undertaking which requires the public to subscribe a very large sum of money, notwithstanding the £90,000 in hand at present. The total cost will exceed a quarter of a million before completion.

**THE NEW PROFESSOR OF MEDICINE IN ST. MUNGO'S COLLEGE.**—Dr. Thomas K. Monro has been appointed to the Chair of Medicine in St. Mungo's College, vacant by the resignation of Dr. Alex. Robertson. Dr. Monro is M.A. and graduated M.B., C.M., at Glasgow in 1888, with commendation, and M.D. with honours in 1895. He was strongly recommended in very flattering terms for the vacant office by Sir Wm. T. Gairdner, whose house physician he was in the Western Infirmary, and also by Professor Osler, of John Hopkins University, Baltimore, who says in his testimonial "that Dr. Monro is well known to us on this side of the Atlantic as an original and careful writer on many medical subjects." After graduating, Dr. Monro studied in Vienna, Berlin, and Paris. His contributions to medical literature are very numerous. St. Mungo's College is to be congratulated on having appointed one to the Chair of Medicine who, in the language of Sir W. T. Gairdner, "will do credit to their choice, and will advance the interest of the College and its students."

### THE FUTURE OF VICTORIA UNIVERSITY.

THE proposed disintegration still continues an engrossing topic for discussion in academic circles. On June 29th an important meeting of the Court was held, at which Earl Spencer, Chancellor of the University, presided, and the following resolution was submitted from University College, Liverpool:—"That while gratefully acknowledging the advantages which have accrued to University College, Liverpool, by its association with Victoria University, this Court is of opinion that a

university should be established in Liverpool, and will welcome a scheme for this object upon an adequate basis." Sir John Hibbert, Chairman of the County Council of Lancashire, Professor Rücker, Mr. A. H. D. Acland, Dr. Clifford Allbutt, and others deprecated a dissolution of the great federal University of the North, and Earl Spencer clearly indicated the dangers which might arise from the establishment of several local universities to the cause of higher education. The best opinion evidently deprecates the impetuosity and ill-directed ambition of Liverpool. Strong feeling exists among graduates that a dissolution of the Victoria University would be an act of injustice to them, and, as Earl Spencer expressed it, is it right or desirable to to break up a university which already had a great many men dependent upon it. A great many men had felt much honour in passing the degrees of that university, said Earl Spencer, and he thought they would be exceedingly sorry if the university to which they belonged, and which had conferred honour upon them, should no longer exist, which would be the case if the Liverpool resolution was carried. The general opinion of the Court was finally voiced by the adoption of the following resolution:—"That in order more fully to deal with the resolution of the Court of University College in reference to the establishment of a university in Liverpool, a Committee of the Court be appointed to consider and report, in the event of an application for a university charter being made by University College, Liverpool, what action, if any, should be taken by the Court of the University, and that the authorities of University College be requested to keep the Committee informed of any steps which they may propose to take in the matter." The irreconcilable attitude of Liverpool is well indicated by the following resolution, which was unanimously adopted at a meeting of the Liverpool City Council on the 3rd inst.:—"That this Council has observed with much satisfaction the growth and progress of the University College, and in view of the fact that the college authorities are taking steps to procure the establishment of a separate university for Liverpool records its opinion that it is desirable, in the interests of higher education in the city, that such a university should be founded." Such an eminently parochial point of view may well distress those who hope for a raised standard of medical education in this country. A serious attempt is apparently to be made to Americanise our system of university education. Medical educationalists throughout the country will do well to watch the proceedings which are quietly taking place with regard to Victoria University, as it seems likely that it is premonitory of a phase of thought and line of action which will have far-reaching results on university training in this country. Meanwhile it would be well if medical graduates of the Victoria University could be associated in a graduates' council to watch proceedings and safeguard their own interests.

## Liverpool.

[FROM OUR OWN CORRESPONDENT.]

### PROPOSED UNIVERSITY FOR LIVERPOOL.

THE proposal of the University College, Liverpool, to separate itself from the Victoria University has come upon the Manchester portion as somewhat of a cold douche. It cannot see any necessity for such a move, and it looks upon the proposal as an evidence of some degree of ingratitude. As regards the attitude and sentiments of the University College section, and indeed of Liverpool generally, there can be no ambiguity. The proposal of the College itself—"That while gratefully acknowledging the advantages that have accrued to University College, Liverpool, by its association with Victoria University, this Court is of opinion that a University should be established in Liverpool, and will welcome a scheme for this object upon an adequate basis"—is evidence of this on the part of the College, whilst the resolution of the City Council, passed at a meeting on the 3rd inst., is sufficient evidence of the feeling of the Liverpool public generally.

No special arguments were employed by the Owens College section against the proposal, but it was quite natural that one of such novelty and one so revolutionary should not meet with immediate acceptance. It would have been too much to expect such a thing. However, the College has done well to bring it forward, and a beginning has been made. Looked at impartially, a good deal may be said in favour of the project. The Liverpool University would be a more self-contained institution, a part of its energies would not have to be frittered away in seeking the co-operation of its other half, and a stimulus would be given to it to do its very best to keep abreast of other institutions.

On the other hand, there appears to be only one objection to it, and that is that it would interfere with vested interests and damage the prestige of the Victoria University by the formation of still another licensing body. This would not be of much moment, however; people who are content with the already absurd number of licensing bodies cannot seriously object to the addition of one or two others. In Germany no University is a licensing body; there is but one portal for practitioners, and that is the State examination. Why not do here what has been done in Germany, and sweep away the power of granting licenses from all the present licensing bodies and make one portal—a State examination? All jealousies on the part of present licensing bodies would then cease, degrees would then become simple academic distinctions, honourable distinctions as much as ever, but the degree would be removed out of the sordid atmosphere of licensing for money and the commercialism inevitably associated with it.

### Literature.

#### MAKINS'S SOUTH AFRICAN WAR SURGERY. (a)

This volume is the outcome of the author's experiences as consulting surgeon to the South African Field Force. As such it forms part of what will be doubtless a copious literature, but it may be questioned whether any individual book is likely to be of greater value to the student of military surgery than the one now before us. Mr. Makins took to his task a ripe experience of surgery gathered from many years of work as surgeon and teacher in St. Thomas's Hospital and elsewhere. He has brought the full extent of his powers to bear upon a systematic examination of the immense mass of material rendered available to military surgeons by the prolonged war that is still dragging its slow length along in South Africa. The question of transport is introduced by the statement that its importance is felt from the time of the injury till the time of the arrival of the patient in the mother country. To the surgeon it is of the same vital importance as the carrying of food for the troops is to the combatant general. This view has a little further on the significant rider that a really satisfactory wagon, combining both strength and comfort, still remains to be devised. Illustrations are given of various wagons, hospital trains, hospital tents, and other details that enable the reader to form a graphic idea of the realities described in the text. The difficulties in the way of the surgeon were numerous. Dust, for instance, was everywhere, and, we are told, "often when a bandage was removed an even layer of dust, moistened by perspiration, covered the whole area included with a coating of mud." Flies were another source of annoyance, and mustered in vast numbers within a few days of the pitching of a camp. Indeed, it is not a little remarkable that, under the circumstances, so little septic mischief was encountered. Curiously, the only really acute case of joint pyæmia heard of by the author developed in connection with a blistered toe, followed by cellulitis of the foot. From a series of observations the author was enabled to arrive at the following definite conclusion as to the alleged use of expanding bullets:—"The opinion I formed was against either the very free

use or the great wounding power of so-called expanding bullets of small calibre. I believe that a great number of the injuries which were attributed to the employment of these missiles were produced either by ricochet regulation bullets of small calibre, or by large leaden bullets of the Martini-Henry type." This opinion is of the utmost value, coming as it does from a trained observer who has availed himself of an unusually wide field of observation. From a surgical point of view the book is full of interest. A striking instance of the absence of initial pain was afforded by a man shot through the buttock, the bullet then traversing the abdomen; this patient remained unaware that he had been hit until on undressing he found blood in his trousers, and exclaimed, "Why, I have got this bloody dysentery!" None the less his internal injuries were sufficiently severe to lead to his death within thirty-six hours. A man shot in the pelvis had an attack of retention of urine on the voyage home, and passed a Mauser bullet per urethram. The radiograms are of great interest, their technical quality is excellent. The illustrations include twenty-five plates and seventy-one process pictures, and add considerably to the value of the book. Regional injuries are dealt with systematically and minutely, and the author may be congratulated on having written a volume that is worthy of the best traditions of British surgery.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

#### THE ANDERSON FUND.\*

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—We shall feel much obliged if you will give us your powerful aid in bringing before the medical profession and the public the following facts in connection with the late Mr. R. B. Anderson, F.R.C.S., whose widow and two orphan sons are now living in Tobago and are in the most straitened circumstances.

A strong representative committee—with power to add to their number—has been formed with the view of appealing for assistance to those members of the medical profession and of the public who knew and sympathised with the hard case of Mr. Anderson which aroused more interest and sympathy than any other professional case of recent years, and raised a most vital point in medical ethics.

Shortly, the history of this case is, that after being for some time in attendance on a private patient in Tobago Mr. Anderson refused to continue his attendance, owing to her husband's personal rudeness to himself. On this an action was brought against him by the patient and her husband, and Chief Justice Gorrie (of Trinidad and Tobago) gave damages against Mr. Anderson for neglect in retiring from the case, although the attendance of another medical man had been immediately secured, and no injury to the patient was proved.

Mr. Anderson resisted this judgment, excessive bail was demanded from him, and in default he was imprisoned, and in the end ruined by this and other illegal acts of judicial oppression. Mr. Anderson then came to England, a Committee was formed to assist him in carrying the West Indian judgments in Appeal to the Privy Council, and Mr. Anderson in person brought an action before the late Chief Justice Coleridge in the Queen's Bench for the recovery of damages against the Colonial Judges. An English special jury gave a general verdict in his favour, with £500 against one of the Judges—Chief Justice Gorrie having died just prior to the trial—but Lord Coleridge gave judgment for the Judge, against Mr. Anderson, and the verdict in his favour, on the ground that no civil action for damages would lie against Judges for acts done in their judicial capacity. This judgment was confirmed on appeal, and from want of funds a further appeal to the House of Lords, and the proposed Colonial Appeal to the Privy Council, were rendered impossible. Finding his legal remedies unsuccessful, owing to the insufficient support he received from the

(a) "Surgical Experiences in South Africa, 1899-1900." By G. H. Makins, F.R.C.S., Surgeon to St. Thomas's Hospital, late Consulting Surgeon to the South African Field Force. London: Smith, Elder and Co. 1901

corporations and associations of the profession, Mr. Anderson began an active campaign of medical reform, by which means alone he saw any hope of proving the justice of his case, and securing for the future the rights of the profession, which were involved in his case, together with others which, in his opinion, required protection.

His life terminated suddenly from heart disease under pathetic circumstances, on November 8th last, and our committee feel that many in the profession, as well as others, will be ready—whether or not they were in agreement with Mr. Anderson's views and methods—to respond to this appeal on behalf of his necessitous family.

Donations "for the late E. B. Anderson Fund" sent, and made payable to the Manager, Union Bank of London, Chancery Lane, London, will be duly acknowledged, and the amount subscribed will be dealt with as our committee, by resolution, may decide.

We are, Sir, yours truly,  
STAMFORD (Chairman).  
TIMOTHY HOLMES (Hon. Sec.)

## Laboratory Notes.

### ESVACH APERIENT WATER.

THE examination of a sample of Esvach Water (Stam and Cross Brand) has shown that it has exactly the same composition as the sample which we examined over two years ago; this being constant greatly enhances its value, as persons using it habitually may thus rely upon always taking the same amount of the aperient salts which this water contains.

It is undoubtedly efficacious for habitual constipation, and the skilful manner in which the ingredients are combined overcomes the griping effects which are so often experienced after the administration of some aperient waters. The excessively bitter taste which frequently leads to the disuse of similar remedies is obviated in an ingenious manner in this water, and bearing in mind the comparatively large quantities of the sulphates of sodium and magnesium which are in solution, this in itself ought to be no small recommendation.

## Medical News.

### The Rontgen Society.

At the annual meeting held July 4th, the following officers and council for the ensuing year were elected. Those marked with an asterisk have not held, during the preceding year, the office for which they are now elected:—President: Herbert Jackson, F.C.S. Vice-Presidents: Lord Blythswood, the Rt. Hon. the Earl of Crawford, D. Ferrier, M.D., F.R.S., J. H. Gladstone, D.Sc., F.R.S., F.C.S., A. A. Campbell Swinton, Dawson Turner, M.D. Council: Barry Blacker, M.D., B.S., J. Mackenzie Davidson, M.B., J. H. Gardiner, F.C.S., A. W. Isenthal, F.R.P.S., E. Payne, M.A., \*C. E. S. Phillips, \*E. W. H. Shenton, L.R.C.P., M.E.C.S., J. J. Vezey, F.R.M.S., H. Snowden Ward, F.R.P.S., J. Wimshurst, F.R.S., Hugh Walsham, M.A., M.D., Chisholm Williams, F.R.C.S. Hon. Treasurer: J. J. Vezey, Esq. Hon. Secretary: F. Harrison Low, M.B.

### A Commission on Butter.

A JOINT Departmental Committee has been appointed to inquire and report as to what regulations, if any, may with advantage be made under section 4 of the Sale of Food and Drugs Act, 1899, for determining what deficiency in any of the normal constituents of butter, or what addition of extraneous matter or proportion of water in any sample of butter, shall, for the purpose of the Sale of Food and Drugs Act, raise a presumption, until the contrary is proved, that the butter is not genuine.

### Lady Doctors Not Required.

FOR over six years the medical staff at Claybury Asylum has included two lady doctors, but the Asylums Committee now state that as "the arrangement is not altogether satisfactory" they have determined to put an

end to it. Recently only one of the lady doctors has been engaged, and she sent in her resignation on learning that it was proposed to abolish the office. The committee propose to make her (Dr. Emily L. Dove), a gratuity of £270 as compensation for the abolition of the office.

### The Oxygen Hospital.

JUDGING from the annual report of the Oxygen Hospital, in Fitzroy Square, this institution continues to demonstrate the fact that an atmosphere of oxygen is strikingly favourable to the repair of certain forms of chronic ulceration. The returns show very clearly that intractable ulcers of the leg do heal in a very remarkable way under its influence, and if this method of treatment has not come into more general use this is doubtless due to the fact that it entails the use of sundry appliances hardly available outside the walls of a hospital. In all, eighty-one cases were treated during the past year, of which fifty-nine were discharged as cured, and twenty-two remain under treatment. The cost per patient per week does not exceed £1 7s., and the average stay in hospital is three months.

### JAN 15 1902 Deaths under Chloroform.

THE first case in which Dr. Waldo, the newly-appointed Coroner for the City of London, had to exercise his functions was that of a lad, aged 12, who died under chloroform at St. Bartholemew's Hospital, after an accident. Death was attributed to the weak state of the patient, and the usual verdict was returned. A similar catastrophe is reported from Barry, the victim being a married woman, age 32, who had been anaesthetised by Dr. O'Donnell prior to the removal of retained membranes after miscarriage. As usual, no details are forthcoming, and the stereotyped verdict was returned.

### The Westmeath Tragedy.

AT Westmeath Assizes last week, Dr. Edward Thomas French was charged with the wilful murder of his wife on April 6th last, at their residence at Glasson, near Athlone. Dr. French was Medical Officer of Glasson District, Athlone Union. From the evidence it appeared that the prisoner, aged about 60, who had been for more than thirty years attached to the Glasson Dispensary District, and who married the deceased lady about twenty-five years ago, was in the habit of drinking to excess, and while under its influence was most excitable. During the evening of April 5th the servants were alarmed by a loud scream, and on rushing to the room observed Mrs. French endeavouring to escape from her husband, who held in one hand a hammer and the other a surgical knife. She said she had been stabbed. The servants caught the doctor and took the knife. Mrs. French ran down some steps to the garden and to the front door, where she fell, and expired in about twenty minutes. There was a deep wound under the right breast, and the liver was pierced and the apex of the heart wounded. For the defence Dr. Fitzgibbon and Mr. Ormsby, F.R.C.S., of Dublin, deposed that the prisoner was suffering for years from a chronic inflammatory disease of the scalp of his head, which undoubtedly would affect his brain, and they believed he was not accountable. Drs. Smart, Shanley, and Kelly corroborated. In charging the jury Lord Justice Holmes said it would be a serious thing to condemn a man who was not responsible, but it would also be a most melancholy thing if they should come to the conclusion that a man was irresponsible when he was actually responsible. The prisoner was a drunkard, and in recent times was more frequently drunk than sober. It was possible that he was a dipsomaniac. His Lordship further said that they could not come to any conclusion from Dr. French's actions during the day of the crime, but that he was perfectly sane. The jury, after a short absence, returned a verdict of guilty of manslaughter. His Lordship said the manslaughter was the most serious one that could be, and sentenced the prisoner to penal servitude for life.

### British Pharmaceutical Conference—The Dublin Meeting.

THE British Pharmaceutical Conference was established in 1863 for the encouragement of pharmaceutical research and the promotion of friendly intercourse and union among pharmacists of the United Kingdom, and

now embraces about 8,000 members. Meetings have been held yearly in different centres, that for 1899 in Plymouth, 1900 in London, and this year the conference have accepted an invitation to hold their meeting in Dublin, it being twenty-two years since a similar visit was paid to the Irish metropolis. The conference commences on Monday, July 29th. Under the presidency of G. C. Druce, Esq., M.A., F.L.S. (Mayor of Oxford) the scientific meetings will be held in the Lecture Theatre of E.D.S., when papers dealing with original investigation of drugs, their adulteration and impurities, will be read and discussed and collections of rare specimens examined. For the enjoyment of the visitors a special programme of entertainments and excursions has been arranged by the Local Reception Committee. At least 400 visitors are expected from across the Channel, and hotel accommodation has been secured for these in the leading hotels. By kind permission of the Right Hon. the Lord Mayor, a luncheon will be given in the Round Room of the Mansion House on Tuesday and Wednesday.

**St. John of Jerusalem.**

MONDAY, June 24th, was the festival of St. John the Baptist, when the members and associates of the Order attended Divine Service at St. John's Church, Clerkenwell, the sermon being preached by the Bishop of Salisbury, one of the chaplains. At the general assembly which took place the same afternoon allusion was made to the great services rendered by the Ambulance Department, and it was mentioned that over two thousand men of the Ambulance Brigade had served as hospital orderlies in attendance on the sick and wounded in South Africa.

**Pass Lists.**

**Royal University of Ireland.**

The undermentioned candidates have passed the First Examination in Medicine, Summer, 1901:—John W. Beirne, Charles D. Bell, Samuel Bradbury, Henry W. Brennan, Herbert W. Carson, Robert Chambers, L.L.B., Robert G. Clements, Robert G. G. Croly, Arthur G. Cummins, James S. Dickey, James Donnelly, John Finnigan, Isaac Flack, James Flack, James B. Hackett, Adam Hill, William J. Hill, Robert Jameson, Sch., Edward Kavanagh, James Kelleher, Robert Ledlie, Andrew Leitch, John Lilley, Robert J. Lytle, Denis T. MacCarthy, William McKee, Albert V. M'Master, Samuel M'Murray, James Magill, Thomas J. Magill, Timothy Meagher, Charlotte E. Mitchell, Timothy O'Driscoll, Michael J. O'Grady, Edward M. O'Neill, John J. O'Reilly, William B. Purdon, Campbell G. Robb, Gabriel V. Ryan, Maurice P. Scanlon, James Shaw, Michael Shipsey, Patrick Stern, William M. Thomson, Stephen M. Walsh, James Warnock, Harry C. Watson, Jemima B. C. White, Wm. R. B. Whitfield.

The undermentioned candidates have qualified on their answering to present themselves for the further Examination for Honours:—John W. Beirne, Charles D. Bell, Samuel Bradbury, Robert Chambers, L.L.B., Robert G. G. Croly, Arthur G. Cummins, James S. Dickey, James Donnelly, James Flack, William J. Hill, Robert Jameson, Sch., Andrew Leitch, Albert V. M'Master, Timothy O'Driscoll, Campbell G. Robb, Gabriel V. Ryan, Maurice P. Scanlon, Patrick Stern, James Warnock, Harry C. Watson.

**Royal College of Physicians and Royal College of Surgeons, Ireland.**

The following candidates have passed the first professional examination A in all subjects:—1. Honours in order of merit: E. L. Sheridan, I. Allau, W. W. Boyce, Miss C. E. O'Meara, R. A. Brown, T. W. Brown. 2. Pass: Alphabetically: A. C. Adams, J. M. Alcorn, E. V. Budge, W. C. Cardon, S. C. Clark, T. Coffey, S. G. Condon, J. Corboy, F. X. Costello, V. J. Cullen, E. F. O'T. Dickenson, T. A. Flynn, D. Hampson, B. C. McC. Hannan, P. E. Hayden, J. M. Hayes, E. Hayes, J. Leonard, E. P. Maher, W. P. Morton, D. McCormack, W. J. McCormack, H. V. McKeogh, A. N. McLaughlin, R. A. Odum, W. C. T. Robey, E. Smith, R. H. Smythe,

P. D. Sullivan, W. Walsh. B. Completed the examination: M. Ambrose, L. L. Davys, T. J. Golding, H. Hosty, D. McLaughlin, T. J. Sinnott, G. B. Spencer, Geo. F. Wright.

**Royal College of Physicians and Surgeons, Ireland.**

The following candidates have passed a special examination for the Diploma in Public Health:—Hampton Atkinson Gray, M.D., Univ. Dubl.; Joseph Patrick Frengley, F.L.C.S.I.; John Grant Warren, L.R.C.P. and S.I.

**Society of Apothecaries of London.**

The following candidates have passed the Primary Examination, Part I.:

Biology.—G. E. Austin, F. C. M. Gabites, C. A. Sampson.

Chemistry.—G. E. Austin, F. C. M. Gabites.

Materia Medica and Pharmacy.—A. Bernfeld, A. G. Gamble, G. B. Messenger, C. A. Sampson, C. J. Taylor, B. B. Westlake.

The following candidates have passed the Primary Examination, Part II.:

Anatomy.—A. J. Ambrose, G. C. M. Davies, B. C. Ghosh, T. W. S. Hills, H. M. Huggins, C. Kellgren, G. Nunn, C. H. Osmond, O. P. N. Pearn, E. H. Price, E. C. Richards, R. J. S. Verity, S. J. Weinberg.

Physiology.—H. Bacon, G. C. M. Davies, B. C. Ghosh, T. W. S. Hills, H. M. Huggins, A. C. Jenkins, T. L. A. Jones, C. Kellgren, G. Nunn, O. P. N. Pearn, E. H. Price, G. H. Rains, B. C. Richards, S. H. Sugden, S. J. Weinberg.

**Navy Medical Service.**

The session of instruction at the Royal Naval Hospital, Haslar, terminated on June 26th, when the fourteen surgeons under instruction, who had obtained their commissions after the competitive examination in London some months previously, received appointments to His Majesty's ships on the determination of their seniority by the sum-total of the marks obtained in London and at Haslar. The following prizes were awarded, viz.: The Gold Medal to Surgeon A. J. Wernet and the Microscope and the Silver Medal and books to Surgeon E. Cox. The Director-General of the Medical Department of the Navy, Sir Henry Norbury, K.C.B., M.D., in distributing them, complimented all the officers highly on the very favourable report which he had received from the Inspector-General and the officers of the professional staff as to the great interest they had shown in the subjects which formed the course, as well as on the general zeal and ability they had evinced during the time they had been under instruction. Surgeons in order of seniority:—

- |                                      |   |
|--------------------------------------|---|
| 1. E. Cox, B.A., M.B. 6,659          | 8. T. F. O'Keeffe, M.B. ... 4,681       |
| 2. J. MacDonald, M.D. 6,168          | 9. E. F. Ellis ... 4,472                |
| 3. A. La P. Darley ... 5,656         | 10. D. V. Lowndes ... 4,250             |
| 4. A. J. Wernet ... 5,631            | 11. G. C. C. Ross, B.A., M.B. ... 4,245 |
| 5. C. E. C. Stanford, M.B. ... 5,203 | 12. P. F. Alderson ... 4,032            |
| 6. A. E. Thomas ... 4,955            | 13. H. C. Woodyatt ... 3,855            |
| 7. W. E. Ruttledge ... 4,826         | 14. J. Thornhill, M.B. 3,848            |

**The Indian Medical Service.**

The following is a list of the surgeons on probation for the Indian Medical Service who have been successful at both the London and Netley examinations. Combined London and Netley marks:—

- |                             |                             |
|-----------------------------|-----------------------------|
| Charles, G. E... 6,168      | Foster, H. B. ... 4,680     |
| M'Kendrick, A. G. ... 5,959 | Butt, G. B. ... 4,544       |
| Moes, O. St. J. ... 5,672   | Kerans, G. C. L. ... 4,507  |
| Little, J. W. ... 5,413     | M'Conaghey, C. B. ... 4,488 |
| Sumner, F. W. ... 5,285     | Illins, H. W. ... 4,395     |
| Nutt, H. B. ... 5,234       | Browne, E. W. ... 4,390     |
| Barnee, J. A. ... 5,073     | Christian, J. B. ... 4,216  |
| Ritohie, W. D. ... 5,014    | Murphy, A. ... 4,161        |
| Scott, N. E. H. ... 4,914   | Thompson, F. T. ... 4,124   |
| Fleming, J. K. S. ... 4,873 | Brassey, L. P. ... 3,881    |
| Hepper, E. C. ... 4,819     | Marr, C. F. ... 3,843       |
| Southon, C. E. ... 4,803    | Box, S. ... 3,761           |
| Fowler, G. ... 4,685        | O'Neill, P. L. ... 3,547    |
| Husband, J. ... 4,680       |                             |

## Notices to Correspondents, Short Letters, &c.

MR. WM. TEBB.—Your letter having already appeared in the lay press it is unnecessary to give space to it in our columns.

TRUTH.—The extraordinary mortality to which you refer in Calcutta was for the week ending March 23rd of present year, when it reached 143.6 per 1,000 of the population, but these figures are valueless for comparison in the other case.

JUNIOR ASSISTANT will find vacancies advertised in our present number under the London County Council, the Metropolitan Asylums Board, Chester General Infirmary, &c., such as he seeks.

### MODERN METHODS!

ELDERLY Practitioner: The child appears to be teething.  
New Graduate: Impossible! The bacteriological diagnosis discloses no trace whatever of the characteristic teething bacillus.—*British and Colonial Druggist.*

DR. JOHN N. SHEE.—The question is a natural one in view of the attitude taken up by this journal on the subject. In reply, it may be stated that the announcement got in by an oversight, and when discovered it was unfortunately too late to withdraw.

ONCEBORN.—The use of the tetanus antitoxin has not proved successful in all cases of tetanus. But the value of it is shown by the fact that it has reduced the mortality in the disease from 90 to 39 per cent.

### A GOOD HOSPITAL STORY.

In a recent number of the *St. Mary's Hospital Gazette* we find the following story told *propos* the resignation of Mr. Critchett: A man having been jammed in a traction engine was brought to the hospital and admitted. As he was suffering from diplopia, Mr. Critchett's advice was sought. Discovering a paralysis of one of the ocular muscles, he gave him large doses of iodide of potassium. The house surgeon wished to try galvanism. After a few weeks the paralysis was cured, and the diplopia had vanished. The house surgeon asked Mr. Critchett which treatment he thought had cured the diplopia. Mr. Critchett said, "I think we might cry, 'honours easy,' for I took him by assault and you by battery."

DI. M. (Bellast).—B Naphthol is a somewhat irritating substance if allowed to come into contact with the walls of the stomach, but it is practically non-toxic, owing to its extreme insolubility in aqueous fluids.

## Diary for the Week.

### ENGLAND.

WEDNESDAY, JULY 10TH.

DERMATOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5.15 p.m. Consultation on cases of clinical interest.

THURSDAY, JULY 11TH.

BRITISH GYNECOLOGICAL SOCIETY (20, Hanover Square, London, W.).—At 8 p.m. Dr. H. P. Noble, of Philadelphia, on "Degenerations and Complications of Uterine Fibromyomata."

FRIDAY, JULY 12TH.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos Street, W.).—Special discussion on "Tumours of the Pharynx," to be opened by Dr. Robert Woods, Dublin. Also cases and specimens by the President, Mr. Mayo Collier, Dr. Barclay Baron, Mr. Lennox Browne, Dr. Dundas Grant, &c.

### IRELAND.

WEDNESDAY, JULY 10TH.

PHARMACEUTICAL SOCIETY.—11 a.m. Examination.

THURSDAY, JULY 11TH.

DUBLIN SANITARY ASSOCIATION (42, Dame Street).—4.30 p.m. Council Meeting.

MONDAY, JULY 15TH.

1st, 2nd, and 3rd Professional Examination, Apothecaries Hall. Final Professional Examination, Royal Colleges Physicians and Surgeons.

## Appointments.

GORDON-SMITH, H., M.A., B.C.Cantab., Resident Medical Officer to the West London Hospital.

GULLAN, A. GORDON, M.D.Lond., F.R.C.S.Eng., L.R.C.P.Lond., Physician to the Stanley Hospital, Liverpool.

HEATHER, LEWIS DANIEL, L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Hay (Brecknockshire) Urban and Rural District Councils.

HICKES, THOMAS, M.B., C.M.Edin., Medical Officer of Health by the Paincastle (Brecknockshire) Rural District Council.

JONES, OWEN CLAYTON, M.B.Oxon., M.R.C.S.Eng., L.S.A., Medical Officer for the Ilfracombe District of the Barnstaple Union.

LITTLEJOHN, THOMAS H., M.B., C.M.Edin., F.R.C.S.Eng., D.P.H., Medical Officer of Health, Hampstead.

MARSH, JOHN HADLEY, M.R.C.S.Eng., L.R.C.P.Lond., Honorary Surgeon to the Macclesfield General Infirmary.

MCCALL, EVA, M.B., Ch.B.Glasg., Assistant Resident Medical Officer at the Birkenhead Union Infirmary.

MCKENZIE, J. M.A., M.B., Ch.B.Aberd., House Surgeon to the West London Hospital.

MOORE, R. G., M.B., Ch.B.Vict., D.P.H.Lond., Medical Officer of Health to the County Borough of Huddersfield.

PENDLEBURY, HERBERT S., F.R.C.S.Eng., Surgeon to the Royal Hospital for Women and Children, Waterloo Bridge, London.

SCOTT, D. WOLSELEY, L.R.C.P., L.R.C.S.Eng., L.F.P. & S.Glasg., Medical Officer to the Hendre Morgern and Henllis Vale Collieries.

SHEILD, A. MARMADUKE, F.R.C.S., Consulting Surgeon to the Royal Hospital for Women and Children, Waterloo Bridge, London.

## Vacancies.

Chester General Infirmary.—House Physician. Salary commencing at £90 per annum, with board, residence, &c. Also a House Surgeon. Salary commencing at £100, with board, residence, &c. Applications to the Chairman of the Board of Management, Secretary's Office, 29, Eastgate Row, Chester. (See advt.)

Croydon Union Infirmary, Maryday Road, Croydon.—Resident Assistant Medical Superintendent and Dispenser. Salary £120 per annum, increasing to £150, with furnished apartments, rations, and washing. Applications to the Clerk of the Guardians.

Cumberland and Westmoreland Asylum, Garlands, Carlisle.—Senior Assistant Medical Officer, unmarried. Salary £150 a year, rising to £180, with board, lodging, &c.

Devon County Asylum, Exminster, near Exeter.—Third Assistant Medical Officer. Salary £125, rising to £150, with board, lodging, &c.

King's College, London.—Professor of General Pathology and Bacteriology. Also Assistant Physician (or Surgeon) for Diseases of the Throat. Conditions and other particulars will be supplied by the Secretary.

Liverpool Port Sanitary Authority.—Assistant Medical Officer of Health. Salary £300 per annum. Further particulars of the Town Clerk, Municipal Buildings, Liverpool.

London County Asylum, Claybury, Woodford Bridge, Essex.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, furnished apartments and washing.

London County Asylum, Banstead.—Medical Superintendent. Salary £1,000 per annum with house, rates, taxes, and water supply free. Forms of application to be hid of the Clerk to the Asylums Board, London County Council. (See advt.)

Metropolitan Asylums Board.—Assistant Medical Officers (unmarried) at the Fever and Small-pox Hospitals. Salary £160 per annum, rising to £200, with board, lodging, attendance, and washing.

Newcastle-upon-Tyne City Lunatic Asylum.—Second Assistant Medical Officer, unmarried. Salary £140 a year rising to £160.

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum, increasing by £15 every year. Also two Assistant Resident Surgeons. Salaries £160 per annum each, increasing by £10 every year, furnished apartments, attendance, light, and fuel. Unmarried.

Owens College, Manchester.—Senior and Junior Demonstrator in Physiology. Stipends £150, rising to £200, and £100 rising to £150 respectively. Applications to the Registrar.

Plymouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200 per annum, with furnished apartments and board and washing. Applications to the Medical Superintendent at the Asylum.

West Riding Asylum, Wadley, near Sheffield.—Third Assistant Medical Officer. Salary £150, with board, &c., rising to £200.

Al-c Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c., rising to £160.

Willesden Urban District Council Isolation Hospital.—Medical Superintendent and Assistant Medical Officer of Health. Salary £350 per annum with allowance of £50 per annum for residence.

## Births.

BENNETTS.—On July 1st, at Bозest, Northants, the wife of F. Bennetts, M.R.C.S., L.R.C.P., of a daughter.

GROSS.—On July 3rd, at 100, Commercial Road, London, E., the wife of Phineas Gross, L.R.C.P.Lond., M.R.C.S.Eng., of a son

## Marriages.

ANDREWS—HORNER.—On July 4th, at the Parish Church, Tonbridge, Henry Arthur Andrews, M.R.C.S., of Tonbridge, fourth son of the late Martindale Andrews, of London, to Amy Diana Frances, only daughter of the late A. C. Horner, M.R.C.S., of Lyons, Tonbridge.

BULL CROOK.—On July 3rd, at the Church of St. Peter and St. Paul, Weobley, Herefordshire, Harry Ashworth Bull, M.R.C.S.Eng., L.R.C.P.Lond., second son of James Bull, J.P., of Birch Hall, Ingestree, Staffs., to Edith Marian, second daughter of the Rev. James Crook, vicar of Weobley.

KIERNEBER MASON.—On July 2nd, at Framfield Parish Church, Sussex, Willie Evan Melfort, only surviving son of H. B. Kierneber, L.R.C.P. and L.R.C.S., Sydney, Australia, to Charlotte Gordon, only surviving daughter of the late Lieut.-Col. E. G. S. Mason, Belfast, Ireland.

## Deaths.

BELL.—On July 5th, at Bedford, after a very short illness, Zebec Stewart, widow of William Bell, M.D., Inspector General of Army Hospitals, aged 74.

HUNTER.—On July 3rd, at the Popters, Pontypridd, Robert Charles Hunter, M.R.C.S., L.R.C.P., J.P., aged 66.

### NÆVI AND THEIR TREATMENT. (a)

By THOMAS H. KELLOCK, M.A., F.R.C.S.,

Assistant Surgeon to the Middlesex Hospital, and to the Great Ormond Street Hospital for Sick Children, London.

It is sometimes profitable and interesting to consider minor subjects which acquire importance from the frequency of their occurrence, and, as in *nævi*, from the good that can so often be done in relieving a patient of what is always unsightly, and, it may be, a cause of considerable inconvenience, for, situate as *nævi* so often are on exposed parts of the body, it is a matter of no little importance to those who have to earn their livelihood, as well as for appearance sake, that these disfigurements should be as far as possible, and as soon as possible, remedied.

Of the *pathology* of *nævi* there is comparatively little to say; structurally they are composed of an agglomeration of slender blood-vessels, with very little muscular tissue in their walls, lined with the usual endothelium, separated from each other, and at the same time bound together, by a small amount of fibrous tissue. The size of these vessels differs in the several varieties; in the superficial ones they are very small, little more than capillaries, whilst in the deeper so-called subcutaneous variety they are often found of considerable size, and in the latter the whole tumour is lobulated and enclosed within a thin capsule of connective tissue, which is not found in those more superficially situated. The circulation of the blood is a little peculiar, arteries lead up to them, and veins carry the blood away, and yet in excising them the vascularity of the surrounding parts is not very great. In the bright red superficial *nævi* the circulation is rapid, as shown by the way in which the colour returns after they have been pressed upon; and if cut into, or penetrated by an ulcer they bleed readily, but owing to the thinness of the vessel walls the hæmorrhage is easily controlled by pressure. In the deeper ones the circulation is not so rapid, as shown by their much darker colour; if cut into, dark blood issues in a feeble stream and the hæmorrhage will often cease spontaneously when the vessels of which they are composed have been emptied. That part of the skin which covers a superficial *nævus* is always badly nourished, in spite of the free circulation underneath, and if ulceration takes place in it from any cause it spreads rapidly and is healed slowly and with difficulty.

Excluding cases of so-called *nævus* of the skin of the legs and other parts which arise in elderly people—women especially—and which are really dilatation of pre-existing veins and capillaries—varicose veins they might more properly be called—and those cases

of angioma of the liver which are said to commence in adult life, but which cannot probably be classed with *nævi*, it may be said that *nævi* are almost without exception congenital; they increase in size, it is true, after birth, rapidly and extensively sometimes, but there is always a something, however small, present at the time of birth. Of their causation little or nothing is known; whether they are hereditary is doubtful, but it is, without doubt, common to find several children in the same family affected. It is a curious fact how many more girls than boys are affected by *nævi*. Of eighty-three cases, fifty-seven were girls, and of ten cases which were so extensive as to necessitate their admission to the hospital for operation during the year 1900, only one was a male child.

*Nævi* are essentially an affection of the epiblastic layer of the embryo. They are found on almost every part of the skin, and on mucous membranes at the orifices where the epiblast turns in to join the hypoblast, as at the mouth and anus. If they occur in the mucous membrane of the alimentary, respiratory or urinary tracts, they do not seem ever to be discovered or to give rise to any symptoms. The following is the order in frequency of the parts of the body affected:—Trunk, face, scalp, upper extremity, lower extremity. The female external genitals are often affected; not so the penis and scrotum, but this may possibly be accounted for by the relative infrequency of *nævi* in male children.

*Nævi* are generally divided into three classes: The superficial cutaneous, or capillary; the deep, subcutaneous, cavernous, or venous; and the mixed, which are a combination of the other two varieties. There are, however, two varieties of the first class which are often seen, the diffuse and the circumscribed. The first of these, the diffuse—perhaps better termed a *nævoid* condition of the skin—is extremely common in very young children, situate in the upper eyelids, on the forehead in the shape of a V, the apex at the root of the nose, and the base at the junction of the forehead and scalp, and also among the hair immediately under the occiput. Of the circumscribed superficial *nævi* there are again two kinds, some—the majority—are *flat*, hardly rising above the level of the surrounding skin; in passing the finger over them except for the sensation of a slight increase in the temperature, hardly any abnormality is recognised. The edges of these are often very irregular, and at times their limitation is not very marked. The others are *raised*, almost pedunculated at times, looking like velvet plush cushions; they are always sharply marked off from the surrounding healthy skin, and are very satisfactorily treated by excision. The deep, subcutaneous, or venous *nævi* generally form darkish coloured tumours which project but slightly on the surface of the body; certain situations, however, modify this, and they may form projecting or even pedunculated masses.

(a) Abstract of a Lecture delivered at the Hospital for Sick Children, Great Ormond Street.

There is a form of deep nævus which is sometimes associated with tumours and new growths. They are generally termed nævi, but can hardly be classed pathologically with those found in the skin; they are composed of a collection of thin-walled vessels which are separated from each other by much more, and much looser, connective tissue than is found in the cutaneous variety, and these vessels are, so to speak, in the direct circulation, not forming a *cul de sac*, as in the case of ordinary nævi; in fact, they are reminiscent of the condition found in a varicocele, and probably the two conditions have a good deal in common. Of such is the collection of vessels found in those rare cases of congenital unilocular cyst of the axilla, forming a pedicle to this, passing up under the clavicle, and connected with the deeper structures in the lower part of the neck.

A superficial nævus may be associated with a tumour of a more important kind. It is quite common to find the base of a spinal meningocele or myelocele surrounded by a superficial nævus, and it is necessary to be careful in dealing with a tumour of the back situated in or near the middle line on whose summit there is a nævus; it may, of course, be only a nævus of the mixed variety, but the superficial nævus may also be a very useful danger signal, for the tumour beneath it may be connected with the spinal meninges or with the spinal cord itself.

Nævi are found, too, in association with other congenital tumours; it is not uncommon to find them in the skin covering hygromata, or in the skin of a limb affected by lymphatic hypertrophy.

Nævo-lipoma is a term used sometimes, but it is a condition rarely seen. The congenital lipomata have peculiarly few blood-vessels, and it is uncommon to find more than the ordinary subcutaneous fat about a deep nævus.

**Prognosis.**—Parents will ask what will happen to the nævus if it be left alone? This question will probably be asked, not about one on the face or other visible part—these they are always naturally anxious to have removed—but about those on the trunks or limbs where they are not likely to be seen. Even these, as a rule, mothers are anxious to have removed, for in the first place they seem to have an idea that any disfiguring mark or deformity in their child is a sort of disgrace to themselves; and secondly, they think that, should a nævus be cut or knocked, the child will bleed to death. The bright red colour has probably something to do with the latter idea, which alarms them unnecessarily, for, although it is true that if cut, bleeding and rather free bleeding does occur, yet the hæmorrhage can be easily stopped by the mildest pressure; at the same time it must be borne in mind in this, as in every other condition, that loss of blood to any extent is always serious in a young body. A more real danger in nævi of any size is ulceration with sloughing and possibly hæmorrhage as a complication. An injury or continued irritation may start this, and once started there is little tendency for it to cease until almost the whole tumour has been destroyed. The ulceration often stops near the edge, leaving a ring of nævus near the healthy skin, and this ring, instead of being destroyed by the ulceration, is apt to be, as it were, stimulated in growth, and to spread outwards into previously unaffected skin. If the nævus be large, ulceration taking place in this way may be serious. On the other hand, if the growth be small and the ulceration extend to its edge, it may result in a cure, but while this is going on there is the danger of sepsis and hæmorrhage, and the cure, after all, is not a very scientific one. It is possible to imagine malignant disease, sarcoma, or epithelioma arising in a nævus. In addition to these dangers there is always the chance of a nævus spreading, and it is rather remarkable how rapidly this sometimes

takes place. A superficial nævus, which at birth is hardly visible may attain a very considerable size in a few months, or even weeks, and a crop of similar growths sometimes springs up around the original one—a good argument in favour of early removal. There seems, however, a limit to their growth, which does not go on indefinitely, but ceases after a time and the tumour becomes stationary. The cause of this cessation of growth is just as obscure as that of its occurrence. The deep nævi very often increase in size after birth, but not nearly to the extent the superficial ones do. These, then, are the risks that are run by leaving a nævus untreated; on the other hand, some of them may spontaneously disappear partially or entirely as the child grows. The nævoid condition about the eyelids, forehead, and occiput always does so, and that too in a relatively short time; if looked for when the child is a year old probably no trace will be found. The deep cavernous nævi rarely, if ever, disappear without treatment, but the diffuse superficial ones sometimes do, and it is not uncommon to watch them getting less bright in colour, although their size may not diminish, and eventually they may become hardly noticeable.

**Treatment.**—There are so many ways of dealing with nævi that perhaps the best plan will be to consider the methods *seriatim*, and under each heading the advantages and disadvantages of the method and the cases for which it is suitable. For, consisting as nævi do of several varieties, and situate as they are on so many parts of the body, no one plan can be adopted for them all, and it is necessary to consider for each which of the various methods should be chosen. **Excision.**—This has the advantage of thoroughly removing the growth at one operation. Union by first intention can be obtained; the scar left is the least possible, and becomes practically imperceptible as the child grows, and there is no danger of recurrence if the excision has been properly carried out. It cannot, of course, be practised in those situations where the necessary drawing together of the skin would cause disfigurement. An anæsthetic is necessary, and the hæmorrhage, even where the greatest care is taken to cut wide of the growth, is often considerable, and not to be too lightly considered in the case of a young baby.

The incisions should be planned so as to be completely clear of the superficial part of the growth, and yet to remove the least possible amount of healthy skin. For the deep ones it is generally possible, by turning back skin flaps, to avoid sacrificing any skin at all. Sometimes two curved incisions, one on either side, sometimes a triangular wound, where the edges are united afterwards in a triradiate fashion, or, again, a quadrilateral wound, united afterwards in "envelope" shape, will answer best. An infant's skin is wonderfully elastic, and it is remarkable how large a growth may be excised in this way and the edges brought together without undue tension, possibly with the help of a little undercutting of the surrounding parts; even if the edges cannot be brought quite together, the remaining surfaces can be grafted immediately, and a very good result be obtained; but if this has to be done it is advisable not to be too free with the suturing, it is better to graft rather more than appears necessary so that the small amount of contraction that takes place under the grafted surface may not cause disfigurement by dragging on an already tightly sutured part. Horsehair sutures are very unirritating, and leave less mark than any others; they should be removed at the earliest possible date, or the little white marks they leave by the side of the scar make the latter more noticeable; a collodion dressing can often with advantage be substituted for the sutures after two or three days

This refers, of course, to operations on visible parts of the body; in other parts the marks do not matter much. There are a few situations where excision cannot very well be carried out, where a nœvus invades the whole thickness of the lips, cheeks, auricle, or eyelids, in the tongue, on the gums, or where it involves important structures, such as the parotid gland; or in a female child where a nœvus involves the breast and excision would mean the sacrifice of the gland, which should not be done unless every other form of treatment is contra-indicated. A common situation for a mixed nœvus is in the scalp over the anterior fontanelle. Here excision is quite suitable; the dangers of interfering with one in that situation have been much exaggerated. They pulsate, it is true, but the pulsation is only communicated, and between them and the superior longitudinal sinus and membranes of the brain there is the thick fibrous membrane closing the fontanelle.

Subcutaneous tumours at either of the fontanelles, at the root of the nose, or at the inner angle of the orbits, may be meningoceles or dermoid cysts, both of which communicate generally with the interior of the skull; these tumours are not so often accompanied by nœvi as the similar ones in the back, but the combination might be met with and lead to great difficulty in treatment if their nature had been overlooked.

*Electrolysis* is another method of treating nœvi. It is a rather tedious performance, painful, and so needing an anæsthetic, probably on many occasions. If, as sometimes happens, sloughing occurs about the spots where the needles were inserted, rather unsightly marks are apt to be left. A large mass of fibrous tissue is often left in the situation of a deep nœvus treated in this way, which is in itself a disfigurement, but which can sometimes be subsequently removed by excision. Electrolysis has the advantage that it is bloodless and can be employed in certain parts of the body where other methods of destruction are contra-indicated, where, for example, a nœvus involves important structures, such as the deep muscles of the face, cheeks, lips, tongue, eyelids, female breast, &c. For superficial nœvi it is rarely needed; if it destroys them it often does so by causing ulceration, and this can be brought about more thoroughly and quickly by other methods if excision is out of the question.

In employing electrolysis there is no need for a very strong current; that from eight to twelve cells is generally sufficient, and the current should be allowed to pass through the growth for from five to ten minutes at a sitting. The needles should be insulated to within half an inch of their points, and passed into the growth far enough to prevent any non-insulated part being in contact with the surface, or ulceration is almost sure to occur at the points of insertion.

*Cauterising Agents.*—The actual cautery, galvano-cautery, and strong acids are useful in destroying superficial nœvi which for some reason cannot be excised.

An anæsthetic is hardly necessary when cauterising a nœvus, especially if it be small. The pain appears to subside very rapidly on the application of a little ointment, or better, dry powder. Whichever of the cauterising agents is employed, it must be done thoroughly, or after a few days the scab that has resulted will come off, and the nœvus be found as vigorous as ever underneath it. For this reason the acids, nitric or sulphuric, are perhaps better than the cautery, as their effect is more penetrating; but they require more care in their application. It is a pitiful thing to see a child's face scarred by acid that has been applied carelessly to a nœvus in infancy; to avoid this, when using any kind of caustic, the surrounding skin should be protected by vaseline or

some simple ointment, and, of course, great care taken that only a very small quantity of the acid is carried by the glass rod or other instrument used. It is hardly necessary to add that especial care in this respect should be taken when operating near the eye. A few of the deep nœvi which cannot be excised, and which do not respond to treatment by electrolysis, may be dealt with by turning back a flap of skin or mucous membrane and inserting the actual or galvano-cautery in different directions, and then the skin flap replaced. A slough will very likely come away if it has been thoroughly done, but the result is sometimes most satisfactory, and the subsequent scarring much less than would have been expected.

*Crushing* a nœvus is a plan that has not much to recommend it.

*Ligatures* was once a recognised mode of dealing with deep nœvi, especially those on the scalp, and in the older text-books on surgery rather elaborate directions are given as to the art of tying the ligatures subcutaneously.

There is also the practice of *injecting* nœvi to cause the coagulation of the blood they contain. Various substances have been used for this purpose, such as perchloride of iron, carbolic acid, &c. It is possible it might be done successfully in a part where it would be feasible to put a clamp or temporary ligature round the growth to prevent the clotting spreading too far, or the clot separating, as in the lips or tongue. The danger of subsequent sloughing must, however, be great, and there are other methods of treatment more scientific and of more proved value.

It is said that small nœvi may be cured by the repeated application of ethyl chloride or collodion, which act by causing contraction of the growth in much the same way as elastic pressure. It would be a tedious way of dealing with them at the best, and it is not much to be wondered at that the method is not much employed.

Neither these substances nor those which ordinarily cause muscular contraction of the walls of the blood-vessels can have much effect on a nœvus in this way, on account of the very small amount of muscular tissue which exists in them.

Of the treatment by *elastic pressure* it can only be said that if it be sufficient to cause effect, that effect would probably be a slough, and if the pressure were not sufficient to produce this, the nœvus would probably be unaffected. To attempt to regulate the pressure of a bandage nicely enough to strike the mean between these, and so cure the nœvus by keeping it empty of blood, is an undertaking that would hardly commend itself.

In conclusion, there is a method of treatment which probably exists more as a popular delusion than as a surgical proceeding, that by vaccination. Owing to the thinness of the walls of the blood-vessels vaccination on a nœvus would be almost sure to cause a little bleeding, which would very likely prevent its success as far as vaccination was concerned, and even if it took it could only cure the nœvus by causing inflammation and sloughing. This might be only partially successful, and might even cause the rest of the growth to spread or multiply, therefore it is much wiser to treat the nœvus by excision or cauterising, and to perform the vaccination on some unaffected part of the body.

#### Royal Appointments.

MESSES. BRAND AND Co. ask us to announce that they have been honoured by the Royal Warrant of Appointment as Purveyors of Concentrated Beef Tea to His Majesty King Edward VII. The honour of being purveyors to H.R.H. the Prince of Wales was held by them for many years.

## THE DIAGNOSIS OF DIAPHRAGMATIC HERNIA. (a)

By E. FLETCHER INGALS, M.D.,  
Of Chicago.

THE diagnosis of diaphragmatic hernia presents many difficulties in the living subject; so great, indeed, are these, that the condition is seldom recognised until operation or death has yielded an ocular demonstration. The affection is found in rare cases at autopsies, and it is occasionally discovered in the dissecting room in bodies dead of other affections, but, all told, only a little over 300 cases have been reported. H. I. Bowditch reported a case in 1847, and at that time collected reports of eighty-eight cases. Leichtenstern (b) reported a case in 1874, and at that time collected reports of 250, but only five of these were diagnosed before death. Thoma (c) collected 290 cases in 1882 and many more have since been reported, but still the obstacles to diagnosis remain, although as shown by Leichtenstern, and by Abel (d) in 1894, there are some cases in which a reasonably positive diagnosis may be made without great difficulty. As I have elsewhere stated (e): "This affection possesses many symptoms and signs in common with pneumothorax, like which it causes distension of one side, displacement of the heart, diminished motion, tympanic resonance and feeble or suppressed respiration with metallic tinkling." The history will often be of the greatest aid in reaching an accurate conclusion. In the cases collected by Bowditch, twenty-six were congenital and the rest traumatic. The principal symptoms noted were dyspnoea on exertion and sometimes on lying down; pain in the bowels, especially after a full meal, in those where the opening through the diaphragm was small, and vomiting in several cases where the stomach was wholly or in part within the chest. In most of the cases the pulse was disturbed and in a few it was weak and rapid. In 27 per cent. of these cases the patients were in good health and engaged in active business.

In Abel's case the symptoms, which came on suddenly, were those of obstruction of the bowel, with vomiting, profound collapse, retraction of the abdomen and distension of the left side. He based his diagnosis upon the retraction of the abdomen, distension of the left side with tympanic resonance and displacement of the heart to the right, with the collapse, and absence of any passages either of gas or feces from the bowels. In his case it was impossible to introduce a stomach tube through the cardiac orifice; therefore this organ could not be irrigated. In Leichtenstern's case he was able to demonstrate the presence of stomach and intestines in the pleural cavity and to note changes in them from the introduction of water and air. This patient complained of dyspnoea on exercise, but worse during eating. There was slight cyanosis of lips, increased respiratory frequency, and almost an absence of heart dulness. Percussion and auscultation over front of thorax yielded normal signs. Heart sounds muffled and loudest at lower end of sternum. Abdomen flattened. Posterior part of thorax: slight loss of motion and prominence below the left shoulder blade. Percussion and auscultation normal to lower angle of left scapula. Below this a hollow, deep, tympanic note. In this region absence of vesicular breathing; instead of this, high-pitched metallic inspiration and expira-

tion, transmitted from the bronchial tubes, the inspiration loudest. Metallic tinkling and succussion sounds part of the time. The exact extent of area of metallic resonance and breath sounds was determined by auscultatory percussion. The borders where the metallic notes ceased abruptly varied considerably at different examinations. At times over the lower part of the chest the metallic breathing and quality of the percussion note would disappear entirely, and the resonance would merely appear exaggerated; at other times it would occupy a larger area and invade the axillary region and even send a tongue-like projection to the left border of the sternum. During percussion the pitch would run up and down the scale from deep to high notes, or the reverse. He believed this the result of peristalsis and emptying of the stomach or colon or filling of same with gas. At times percussion produced notes of varying pitch at different parts of the affected area indicating more than one cavity. At the lower part of the left and back of the thorax dulness would be noted at times. The border of this would change with changes in position of patient. (Contents of stomach.) He based his diagnosis on the following points: Percussion showed in the lower left side of thorax behind a hollow cavity that applied itself to the chest wall in a changeable area. It changes its position, shape, and volume in a very short time. The circumstance that at times metallic resonance was absent in the affected area while there was also absence of fremitus and vesicular breathing at all times over the area, showed that the cavity persisted, but the metallic resonance was lost because of filling of the cavity with contents or because of its contraction. When this contraction occurred the lung tissue and vesicular breathing encroached on the area of the cavity, the lung expanding and following it up. The shifting of the upper border of the area of dulness showed that the cavity contained at times movable contents, and the size of this area indicated the presence of the stomach. The different pitch of certain areas of metallic percussion that at times were separated from each other by areas of dulness was explained by the presence of more than one cavity. (Small intestine, colon, stomach.) The breath sounds over the area were either metallic or often absent. The respiratory sounds he thought were changed in quality and acquired a metallic character by transmission through smooth-walled cavities. The pitch of the metallic breathing was decidedly less intense than that heard in the pneumothorax, because the sound was not transmitted through the pleural cavity alone, but also through the gastric and intestinal walls. At times the metallic breathing was heard only with inspiration, whereas, in pneumothorax, on account of greater compression of the lung, the expiratory sound is the loudest. In addition, gurgling, either simple or metallic in quality was heard, also the metallic tinkling and splashing sounds, with bursting bubbles, trickling and pouring sounds, such as are heard in diarrhoea or ecstasis of the stomach. These sounds were at times very frequent, at other times absent. Leichtenstern argued that where similar sounds are heard in the normal thorax in the axillary and infra-scapular regions if the stethoscope is applied to the stomach or intestines, it can be readily shown that these sounds are far more intense in the normal situation of these organs, whereas in diaphragmatic hernia the dislocation of the intestines or stomach encourages the formation of peristaltic sounds through the place of communication of thorax and abdomen, and these sounds are louder by far in the thorax than they are when listened for over the abdomen. After old pleurisy with high location of the diaphragm the

stomach and intestines can occupy a high situation, but here we have a retracted and not distended thorax, with scoliosis, &c. Succussion sounds in this case showed the variable character belonging to all the other signs. When they were present they were deep, showing a large cavity. (Stomach.)

Almost all reported cases of diaphragmatic hernia show great variability in the signs.

Pneumothorax, the affection with which diaphragmatic hernia is likely to be confounded, results from pulmonary tuberculosis in 90 per cent. of all cases and in probably all of these is speedily followed by effusion of serum or pus into the pleural sac. The affection develops without the history of an injury. In the remaining 10 per cent. nearly all result from traumatism, and in most of these inflammation of the pleura speedily follows with effusion of fluid, though in a very few there may be no infection and the air may be absorbed without causing any effusion. In pneumothorax dyspnoea may come on suddenly or gradually, and we may often hear amphoric respiration, especially in expiration, which may be either intense or feeble, and which disappears when fluid rises high enough to cover the opening into the air passages. When fluid and air are present in the pleural cavity we may often hear metallic tinkling during the respiratory acts, and we may obtain distinct splashing sounds by shaking the patient's body while the ear is applied to the chest. The heart is constantly crowded to the opposite side, where it remains without variation. Diaphragmatic hernia is congenital or occurs through congenital defects in about 38 per cent. of the cases that have been recorded and in many of these it does not cause marked symptoms unless the hernia becomes strangulated. In about 60 per cent. of cases the affection is traumatic and therefore the history is quite different from that of pneumothorax. The dyspnoea in hernia may come on suddenly, and as suddenly subside, whereas, that of pneumothorax is more continuous. I have elsewhere stated that there is no amphoric respiration in diaphragmatic hernia, but the reverse of this is maintained by others. I cannot understand how typical amphoric respiration could be produced in diaphragmatic hernia, although I know that similar though more distant sounds, especially on inspiration, are sometimes heard. These, I believe, are caused by the transmission of the bronchial sounds through the intestines or stomach, some parts of which are distended by gas. The most important factors in the differentiation of non-strangulated cases are the following:—

1. The metallic tinkling in pneumo-hydrothorax and a similar sound, though different in quality, may be heard at times in diaphragmatic hernia. The quality of the sounds produced in the bowels and in the pleural cavity would often be sufficient to differentiate between them, but this quality cannot be accurately described; therefore the principal value of the sign depends upon the fact that in pneumo-hydrothorax it is heard only with respiratory movements or upon shaking the body, while with the hernia it occurs independently of these movements and is associated with rumbling or gurgling of gas in the stomach or bowels which have escaped into the pleura.

2. The displacement of the heart, which in pneumothorax remains practically constant, in diaphragmatic hernia may vary with the varying contents of the stomach or bowels, as when the patient is fasting or soon after eating or drinking freely. The retraction of the abdomen may prove of some value as a sign, and the symptoms of obstruction will be of the utmost importance if strangulation occurs. In a case saved by operation that was recently reported by E. W. Walker, there was the history of a severe injury, with symptoms of intestinal obstruction and

“diminished expansion of the left side of the chest, tympanitic resonance at the base of the left lung, amphoric breathing, succussion sound on shaking the patient and the apex of the heart was displaced two inches to the right.” In this case there had been a fracture of two ribs and the patient had some pain in the left side, which leads one to suspect a rupture of the lung with pneumothorax, in addition to the knuckle of bowel (involving eight inches of the gut) which was firmly held in the rent in the diaphragm. Walker cites numerous authors and states that among the symptoms named, dyspnoea, intense pain, and cough are the most prominent, and that typanitic resonance over the prolapsed gut, amphoric tinkling and sometimes succussion sounds are present.

The symptoms and signs must necessarily vary greatly according to the cause, the nature of the injury, when traumatic, and the condition of the organs protruding from the abdominal cavity. Larcher found that in about 91 per cent. of 275 cases no hernial sac existed. The signs would doubtless vary considerably in the cases in which the intestines protruded freely into the pleural cavity and in those where they were held down by the overlying pleura.

## THE CAUSE OF DIFFUSE PERITONITIS COMPLICATING APPENDICITIS AND ITS PREVENTION. (a)

By A. J. OCHSNER, M.D.,  
Of Chicago.

EVERY surgeon who treats patients suffering from acute appendicitis must be impressed with the fact that an unfavourable outcome in any given case means that the infection which was originally confined to the small space occupied by the vermiform appendix itself has first invaded the tissues immediately surrounding this organ and has been distributed over the entire peritoneal cavity. In other words, in fatal cases the patient practically always dies as the result of a diffuse peritonitis.

Other conditions may arise which may result in a fatal issue. There may be a septic thrombosis of the vessels in the vicinity of the appendix or an empyæma, or even pyæmia, but by far the greatest number of deaths occurs from diffuse peritonitis, and if it is possible to prevent this, the mortality from appendicitis must at once fall enormously. In order to plan a means for the prevention of this condition, it is well to study the progress of the disease from its onset.

There is danger of the occurrence of diffuse peritonitis in the following classes of cases:—(1) In gangrenous appendicitis; (2) in perforative appendicitis; (3) in cases in which the caecal end of the lumen of the appendix is closed and the distal portion so thoroughly distended with septic material as to make its walls permeable to micro-organisms; (4) in the very rare cases in which there are small abscesses in the walls of the appendix not directly connected with its lumen, and (5) in cases in which there is a septic thrombosis of some of the vessels, but not sufficient to cause gangrene.

The first, second, and third conditions are so common that every surgeon who operates frequently during the acute attack has seen them many times.

Were it possible to keep the septic material in these cases within the circumscribed area in which it

(a) Address delivered before the Section on Surgery and Anatomy, at the Fifty-second Annual Meeting of the A.M.A., at St. Paul, Minn., June 4th to 7th, 1901.

occurs primarily, it is plain that the condition would remain comparatively harmless.

The appendix is virtually surrounded on all sides excepting in the direction of the median line by relatively fixed tissues. Above we find the lower end of the cæcum and the cæcal end of the ileum; to the right and in front is the parietal peritoneum; behind the peritoneum covering the iliacus muscle, and towards the median line it is surrounded by loops of small intestines. Moreover, the omentum extends far beyond its lower end. It is true that the appendix may be displaced downwards, but in this case it will again be surrounded by fixed tissues which seem especially adapted to dispose of septic material. Again in this case there is an enteroptosis affecting the cæcum, and always with this a marked lowering of the transverse colon and stomach and with these the omentum. Thus we see that the natural anatomical arrangement for the protection of the general peritoneal cavity is extremely efficient. There is but one weak point in the anatomical provision for this protection, namely, in the direction of the median line, because the great mobility of the small intestines naturally favours the distribution of septic material to all parts of the peritoneal cavity. If we can prevent the small intestines from doing harm in this direction we will have accomplished our end, theoretically at least.

At this point I wish to direct your attention to another important anatomical condition. The blood supply of the omentum is so enormous that it will readily dispose of a very severe infection by walling off the surrounding structures if it is permitted to give its physiological attention to a single area. It is a well-known fact which every one who frequently operates during the acute attack of appendicitis has had many opportunities to observe, that the omentum crowds itself about any inflammatory or traumatic lesion within the peritoneal cavity the moment the latter occurs, and if left undisturbed, a few hours will suffice to cause efficient protective adhesions. These adhesions become stronger every hour and the blood supply in the omentum becomes greater, so that if no disturbance arises one can reasonably expect efficient protection to the general peritoneal cavity from the omentum.

Another important fact must not be lost sight of in this connection. The fact that the surrounding structures are relatively fixed in position favours the condition of rest of the inflamed part and permits the omentum to act after the manner of a splint applied to an inflamed joint. The value of rest as a preventive to the extension of an infection in any part of the body cannot be over-estimated. Consequently, if it is possible for us to secure this condition of rest we have gained another important point in the right direction.

In case the appendix is displaced upwards its position is even more favourable, because the available amount of omentum is thus increased. Again, if the appendix is retro-cæcal in its position, which is very frequently the case, the infection of the general peritoneal cavity is more easily prevented than when in its normal location. If anteriorly misplaced, it is likely to be fastened to the anterior abdominal wall by the adherent omentum.

It is plain, then, that the infection of the general peritoneal cavity must occur from a disturbance on the part of the small intestines, and must be due to their peristaltic motion. It is significant that in almost all cases of severe acute appendicitis the obstruction to the passage of gas and intestinal contents through the ileo-cæcal valve is one of the early symptoms. Nature is trying to prevent this very dangerous disturbance by closure of the ileo-cæcal valve. We have a condition corresponding to the contraction of the muscles surrounding an inflamed

joint, to the closure of the eyelids in conjunctivitis, &c. Moreover, the muscles overlying the appendix become tense. Everything tends toward the establishment of conditions of rest in the vicinity of the inflamed organ.

It is a fact which has been demonstrated a great number of times that peristalsis does not occur unless food or cathartics are introduced into the stomach. If the attack occurs shortly after a meal and before all of the food has passed through the ileo-cæcal valve, its presence may cause peristaltic motion in the small intestines. Upon reaching the ileo-cæcal valve the latter may prevent its passage into the cæcum, causing return peristalsis, and the intestinal contents are forced back into the stomach, whence it may be expelled by vomiting or be again forced into the small intestine, giving rise to further peristaltic motion. Moreover, it will give rise to the formation of gas, which must cause disturbance and pain in its attempt to pass the ileo-cæcal valve.

This motion, it is plain, will be harmful primarily from the fact that it gives rise to pain by disturbing the sensitive inflamed tissues; and secondarily from its likelihood of carrying infectious material with which it has come in contact in the vicinity of the inflamed appendix to other parts of the peritoneal cavity.

Besides this the physiological attention of the omentum can now no longer be directed to the single area of infection, because other parts of the peritoneal cavity require its protection, and such portions of the omentum as are not yet thoroughly adherent about the inflamed appendix are likely to be diverted from this point.

Theoretically, then, the disturbance which is to be feared to so great an extent is caused by the presence of food or cathartics in the stomach, and its logical remedy would be to absolutely prevent the introduction of any form of food or cathartics into the stomach and the removal by gastric lavage of any portion of food which may be retained in the stomach at the beginning of the attack. It may be necessary to perform gastric lavage twice or at most three times in order to entirely remove remnants of food which may have regurgitated into the stomach from the small intestines by reason of return peristalsis. That this is not only true theoretically, but also in practice, I have demonstrated in a large number of cases; and many other surgeons who have followed the same plan of treatment have informed me of the fact that their experience has agreed with mine.

It is true that a few surgeons have reported failures with this method, but an investigation of their treatment in each instance has shown that they disregarded one of the three cardinal points in the treatment. They either gave just a little liquid food by the mouth, or they gave some form of cathartics, or disturbed the rest of the intestines by giving large enemata, or they neglected removing the stomach contents by gastric lavage. Of course, the slightest amount of food is sufficient to start peristaltic motion of the small intestines, and the same is true of cathartics, and consequently if either of these features in the treatment is omitted one cannot hope for the same results. It does not matter what form of appendicitis may be present in any given case, it seems clear that this form of treatment must be useful, because in the milder cases it will result in rest of the affected part, and consequent rapid resolution; while in the severe cases it will guard against mechanical distribution of infectious material, and in all cases it reduces the tendency to meteorism and stops the pain.

There is, however, one class of patients in which I have found this treatment of the greatest value. I refer to the class in which the appendix is gangrenous

or perforated, and in which there is already a beginning general peritonitis. These patients give the impression of being extremely ill. There is complete obstruction to the passage of gas or feces. There is nausea or vomiting and marked meteorism; the pulse is small and quick; usually there is high fever, but the temperature may be subnormal; respiration is rapid, and the abdominal muscles overlying the appendix are tense. The patient is in a condition in which I formerly operated at once, day or night, as a last resort, only to find that it was too late in more than one-third of the number of cases, the mortality increasing with the time that had elapsed since the beginning of the attack. In this class of cases there is still a recovery of over 90 per cent. if the principles laid down above are thoroughly applied.

If peristalsis is absolutely inhibited, as it can be, the infection will soon become circumscribed and the pus can be evacuated with safety. Moreover, the condition I have just described is in itself the result of the administration of food and cathartics. Had these patients received neither food nor cathartics from the beginning of their attack, the condition would never have advanced to this dangerous point. This refers particularly to a class of cases which Richardson has so well described as "too late for an early and too early for a late operation."

If the plan I have outlined above is carried out, the following changes are likely to occur:—The nausea and vomiting will cease after one or two, or at the most three, gastric irrigations. The meteorism and the pain will decrease greatly during the first twelve hours, and will almost completely disappear in twenty-four hours. The pulse becomes slower and firmer and more regular, the breathing deeper, and the patient's general appearance improves to an astonishing extent. If the temperature was high, it will go below 100° F. the first twenty-four hours, and in three days it will be practically normal. The abdominal muscles will become soft as soon as the stomach contents have been removed by gastric lavage. Usually the improvement is so rapid that one is tempted to spoil everything by giving nourishment by mouth, because the patient's condition does not seem serious enough to warrant such severe measures.

That this form of treatment, which I have employed since 1892, at first only in selected cases, and later more and more generally, is really of great value is shown by clinical results. My mortality in cases of perforative or gangrenous appendicitis with beginning diffuse peritonitis is less than one-fourth as high as it was in the cases operated at once upon making the diagnosis, and even in advanced cases of diffuse peritonitis there has been a marked decrease in the mortality in my experience. It might be said that these cases were not due to perforated or gangrenous appendicitis, but that they were simply severe catarrhal cases, which are known to result favourably under any form of treatment. To this I would respond, that I have later removed the appendices in many of these cases, and have almost invariably demonstrated the correctness of the diagnosis.

In my statistics I utilise only the cases which I have operated in the Augustana Hospital, because of these I have full and accurate records, while of those operated in other hospitals and in private homes my records are not accurate, because there the patients and assistants are not so completely under my control. From Jan. 1st, 1898, to May 1st, 1901, I have operated in this hospital upon 565 appendicitis cases, which I have divided into three groups: 1, those who entered the hospital suffering from diffuse peritonitis; 2, those who entered the hospital suffering from gangrenous or perforative appendicitis, and 3, those who entered the hospital suffering from recur-

rent appendicitis in the interval between attacks or at the beginning of a recurrent attack when the infectious material was still confined to the appendix. Of the first class I treated 18 cases, with 10 deaths, 55.5 per cent. mortality; of the second class I operated 179 cases, with 9 deaths, 5 per cent. mortality; of the third class I operated 368 cases, with one death, 1.3 per cent. mortality. Total, 565 cases, with 20 deaths, 3.5 per cent. mortality. The statistics contain all patients who entered the hospital suffering from appendicitis; even those who died a few hours after admission.

Of Classes 2 and 3, all were operated, so there can be no doubt concerning their diagnosis. Of Class 1 all but 4 were operated, and these were in an absolutely hopeless condition when they entered the hospital. I will state also that during this time no patient suffering from appendicitis was refused admission into the hospital.

Judging from the authorities upon this subject, our mortality of 55.5 per cent. in diffuse peritonitis is as low as that recorded by any of the authors whose statistics contain a considerable number of these cases, while some authors with less than half this number report as low as 20 per cent. mortality. Krogus has compiled the statistics of fifty-eight authors whose combined mortality is a little over 70 per cent.

As compared with my own experience in former years, when all of these cases were treated surgically at once, my experience in this series of cases of diffuse peritonitis following appendicitis is quite encouraging.

It is in the second class, however, in which the greatest benefit from the treatment is found. In this class, according to most modern authorities, Murphy, Mynter, Porter, Lennander, Bull, and many others, there is a mortality of at least 20 per cent. This in my cases has been reduced to 5 per cent.; and had the treatment been instituted at the beginning of the attack, I am certain that the mortality could easily have been reduced to one-half of this. In Class 3 there should have been no death. Many of these cases had been treated through their acute attack by the method I have described, before being sent to the hospital. But as not all of the cases I treated outside of the hospital came later to operation, it is not fair to utilise these in demonstrating the value of the method.

Again, I have treated a large number of cases through the acute attack of appendicitis with this method which have never been operated, and which I have not included in my statistics, because the correctness of the diagnosis could not be established by actually demonstrating the condition present in the appendix.

However, the fact that there was a mortality of less than one-third per cent. in so large a number of cases is significant. It shows the value of a method by which cases of acute appendicitis in whom an operation is bound to give a high mortality at best, can be changed to chronic appendicitis in which the mortality following operation is almost nothing. It is, of course, not possible to come to any definite conclusions from a collection of statistics, because there are so many differences which can not be balanced.

Among these cases one is especially instructive because it illustrates the danger of operating too early. The patient entered the hospital five days after the beginning of the attack. His condition was exceedingly grave, as indicated in the history. With an immediate operation I should have expected his death within thirty-six hours. The diagnosis was made of gangrenous appendicitis. He was placed on exclusive rectal feeding. Within twenty-four hours his pain had entirely disappeared, his general

appearance improved greatly, the meteorism subsided, his temperature fell three degrees, his pulse came down forty beats per minute, his abdominal wall became soft, and twenty-four hours later I began to doubt my diagnosis. At the end of the fourth day his condition had improved so much that, upon his request, I concluded to operate, because he was normal in every respect with the exception of a slight induration in the region of the appendix and pain upon deep pressure. It seemed to me as though the process must have stopped just short of a perforation. Had he been left without an operation there could be no doubt but what he would recover temporarily from his attack. It seemed perfectly safe to operate. Upon opening the abdomen I found a perforated gangrenous appendix surrounded by a small abscess completely walled off by the omentum. I removed the appendix and the surrounding pus with great care, and drained the cavity, expecting the patient to recover, but a diffuse peritonitis developed, from which he died five days later. This case impresses the lesson that it is not wise to operate until the patient has fully recovered from the acute attack. Of course, he should be cautioned as regards his diet in order to prevent a recurrence, but I am confident that the mortality in my practice will be still smaller in the future, especially because I shall wait longer after the acute attack before removing the appendix.

The danger of rupture of a circumscribed abscess into the general peritoneal cavity has been the cause of great anxiety. My experience has led me to conclude that this practically never happens unless food or cathartics are given by the mouth. In my entire experience it has happened but once, in a child, *æt.* 7, which was brought to the hospital on the fifth day after the beginning of an attack of gangrenous appendicitis with beginning diffuse peritonitis. It had received food and cathartics constantly since the beginning of the attack, and although its condition seemed hopeless either with or without an operation, it improved slightly from day to day under exclusive rectal feeding, but never became well enough to make drainage of rather an extensive infection of the entire area between the umbilicus and pubis and right anterior superior spine of the ilium safe, and still, had I anticipated the likelihood of a rupture into the remaining portion of the peritoneal cavity, I should certainly have made the attempt with the hope of bringing about a recovery. On the fifth day the abscess suddenly ruptured. I anaesthetised the boy within half-an-hour, made a free incision, washed out the peritoneal cavity, drained freely, but the child died in six hours. In this case gastric lavage had not been employed because the child was very nervous and we feared the effects of the fright. I have frequently seen cases in which food and cathartics were given in whom this accident occurred.

Aside from the benefit to the patient of increased safety there are other advantages to be derived from this plan of treatment, which are well worth considering. Being able to operate during the quiescent state, drainage is not indicated, and consequently there is no likelihood of the occurrence of post-operative ventral hernia. With the reduction of the area of infection the amount of peritoneal adhesions must necessarily be reduced. As a matter of experience I can say that *fecal fistulae* almost never occur in cases treated by this method.

Of course, all these advantages, as well as the prevention of diffuse peritonitis, can be accomplished if the appendix is removed during the very beginning of the attack, before the infectious material has passed beyond the walls of the appendix, but unfortunately it is but very seldom that a patient enters the hands of a surgeon at so early a stage.

I am positive that the mortality would have been

at least four times as great had all my patients been operated at once, upon admission. There are three cases which do not properly belong in this group, because perforation had not actually taken place, but I am confident that this was only prevented by the treatment. Moreover, each one of these cases had quite advanced peritonitis at the time of admission, which would undoubtedly have progressed rapidly had not peristalsis been inhibited. In each of these cases the attack was exceedingly violent until this form of treatment was instituted, but subsided very promptly after commencement of this treatment.

*Conclusions.*—As a result of my clinical observations I am prepared to formulate the following conclusions:—

1. Peristaltic motion of the small intestines is the chief means of carrying the infection from the perforated or gangrenous appendix to the other portions of the peritoneum, changing a circumscribed into a general peritonitis.

2. This can be prevented by prohibiting the use of every kind of food and cathartics by mouth, and by employing gastric lavage in every case in which there are remnants of food in the stomach or in the intestines above the ileo-cæcal valve, as indicated by the presence of nausea, or vomiting, or meteorism.

3. The patient can be supported by the use of concentrated predigested food administered as enemata, not oftener than once in four hours, and not in larger quantities than four ounces at a time.

4. This form of treatment, when instituted early, will change the most violent and dangerous form of acute perforative or gangrenous appendicitis into a comparatively mild and harmless form.

5. Cases of perforative or gangrenous appendicitis, with beginning general peritonitis, can usually be carried through the acute attack safely with this method.

6. In all cases of this class gastric lavage should be practised in order to prevent the absorption of decomposing material from the alimentary canal.

7. In cases of doubtful diagnosis this form of treatment should always be employed.

8. This treatment will prevent a large proportion of the most troublesome complications and sequelæ of appendicitis, such as ventral hernia, *fecal fistulae*, extensive adhesions, &c.

9. The patient should be permitted to recover fully from his acute attack before an operation is performed, except in cases encountered within the first thirty-six hours after the beginning of an attack or in case of the formation of a superficial circumscribed abscess.

10. It often requires but a small amount of any kind of food to change a harmless circumscribed into a dangerous diffuse peritonitis.

11. The treatment does not protect the patient against a subsequent attack.

12. It does not contraindicate the removal of a diseased appendix before the septic material has extended beyond this organ.

13. It is indicated in all intra-abdominal conditions in which it is desirable to prevent the distribution of septic material by means of peristaltic motion.

14. The laity should be taught to stop feeding and giving cathartics to patients suffering from intra-abdominal diseases.

A FATAL case of small-pox is reported in Dundee. During the recent outbreak cases were for the most part of a mild type, and when the epidemic was at its height the city enjoyed a complete immunity from deaths. The first having now occurred, the other inmates of the dwelling have been removed to the reception house for observation,

## FEMORAL CYSTOCELE.

By Dr. RACOVICIANO,

Bucharest.

IN 1898 I had the honour to draw your attention to three cases of inguinal cystocele which I then presented to the Society. At the same time M. Aurin presented his paper on the subject, citing five cases which had occurred in one practice. I have said that in the records of medicine two cases of pure cystocele (a) are not to be found, the majority being cases of cysto-enterocele.

This complication of hernia is serious. To point out any characteristic signs of the bladder is difficult, owing to its physical state being so changed from the normal, and, in some cases, the vesical walls are torn during the earlier steps of the operation. Within my personal knowledge I can speak of two cases where the vesical walls were so thin as to tear, and were incapable of holding sutures, any attempt to secure which caused them to come through. This breakdown of the tissues was accompanied by a bleeding, which terminated fatally.

A case is published by M. Roux, and another by M. Flaquemont, in which a diverticulum of the bladder was mistaken for a hernial sac and resected. Mr. Feriger, of Chicago, cites seven cases in which he produced vesical fistulas, all of which did well. He considers the accident very common, not serious, one from which he has never seen a death. In my first case in 1894 I recollect a diverticulum of the bladder, which I mistook for a hernial sac, the viscus extracted, the ligature fell off, urine escaped into the fundus of the belly, and the patient died.

To-day I wish to bring under your notice a case of femoral cystocele complicating an irreducible enterocele. The patient, a servant, *æt.* 45, has been suffering for some time from an irreducible femoral hernia. He never complained of any bladder trouble, he passes his water in a full stream, and his prostate is but slightly increased in size. During the operation there appeared a second pouch which caused me to suspect the possibility of the bladder being engaged. To test this I now injected the bladder with fluid and passed in a sound, but without effect. I now enlarged the opening, replaced the suspected pouch in the belly, and again used the metallic sound which I now could readily feel with my finger through the vesical wall. By this manoeuvre I satisfied myself that the second pouch was the urinary bladder. These cases are rare. Jaboulais in Delbet's Pathology quotes the theses of De Legmud, which gives thirteen cases, and gives in detail two cases, one by himself and one by M. Aue, published in the *Centralblatt für Chirurgie*, which with our own makes sixteen cases in all. I do not know how many of these were women.

I consider this case important, and I think it right to report such complications as occur in hernias, inguinal and femoral, so that the risk of injury to the bladder by cutting or tearing may be avoided; for, as I have shown, such injuries are sometimes mortal. And, lastly, I may add that I have had the opinion that such a complication in inguinal hernia in women must be very unusual—indeed, I was sceptical as to its existence in woman, when on June 3th, 1899, operating on the woman, M.M., for an inguinal enterocele, I came on an inguinal cystocele. (*Bulletins et Mémoire de la Société de Chirurgie de Bucharest. Tome IV., No. 1.*)

(a) In this, M. Racoviciano is not accurate; there are more than two on record, the majority of which escaped notice during life, because pure cystocele is, as a rule, not painful.—Ed.

## Transactions of Societies.

## SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

THE provincial meeting of this society was held on June 29th at the Medical Institution, Liverpool,

Mr. ROBERT JONES, F.R.C.S., in the chair.

Clinical cases were demonstrated by the Chairman, Dr. Logan, Mr. R. W. Monsarrat, Dr. Macalister, Dr. Lloyd Roberts, Mr. W. Thelwall Thomas, Dr. James Barr, Dr. Stopford Taylor, Dr. Nathan Raw, and Mr. G. P. Newbolt.

Dr. HENRY ASHBY (Manchester) related a case of so-called fetal rickets. The mother was forty-six years of age, and the infant was her fourteenth, born at term, and well nourished. When seen at two weeks there was cranio-tabes, deformed chest walls, and five fractures, including both humeri, left radius, right ulna, and left femur. Three weeks later the right femur fractured. The infant eventually made a complete recovery. Dr. Ashby doubted if such cases were examples of true rickets, but rather resembled the osteoporosis produced by feeding puppies on food deficient in salts of lime.

Dr. RICHARD CATON (Liverpool) read a paper on

## THE TREATMENT OF ENDOCARDITIS,

based upon about 600 cases of that disease occurring in acute rheumatism and chorea. He advocated (a) absolute rest in bed for several weeks; (b) the application of a series of small blisters in the region of the first four dorsal nerves in front, followed by poulticing; and (c) the internal administration of sodium iodide. To be of service this treatment must be commenced within the first fortnight or so.

Dr. WILLIAM CARTER bore testimony to the great utility of the method.

Dr. A. ERNEST SANSOM thought blisters a little less than worthless in endocarditis.

Dr. C. I. MACALISTER advocated blistering and rest both in endocarditis and in pericarditis. Instead of a blister an ointment of the red iodide of mercury (1 in 8) might be employed.

Dr. JAMES BARR spoke of the good effects obtained from blisters in the treatment of acute rheumatism.

Dr. H. E. HUTTON testified to the rapid disappearance of pericarditis under blistering.

Dr. CATON, in reply, said that in acute rheumatism he used the salicylates along with small blisters to the joints.

Dr. GEORGE CARPENTER and Mr. SYDNEY STEPHENSON read a paper upon

## TUBERCULOSIS OF THE CHOROID,

based upon the examination of forty-nine cases of the kind. The lesions were found ophthalmoscopically in twenty-one out of forty-two cases of acute tuberculosis and tuberculous meningitis, or in exactly 50 per cent. In 119 cases of chronic tuberculosis, choroidal changes were discovered in no less than 9·2 per cent. In quiescent tubercle they were also found. The author described the characters of the choroidal tubercles, and pointed out the great diagnostic value of the growths. The communication was illustrated by microscopical preparations and by numerous paintings of diseased eyes.

Dr. A. ERNEST SANSOM and Dr. HENRY ASHBY discussed the paper.

Dr. WARRINGTON asked whether tubercles in the choroid were observed except in the last stage of illness.

Dr. GEORGE CARPENTER, in reply, said that in the acute cases mentioned in the paper tubercles were found in the choroid from one day to six weeks before death. Tubercle in the choroid did not necessarily warrant a grave prognosis, since some of the cases became obsolescent.

Dr. D. M. HUTTON (Southport) read a note on a case of

## SYPHILIS TRANSMITTED TO THE THIRD GENERATION.

The grandfather produced a certificate before his marriage certifying that having had syphilis he was cured.

The mother suffered from specific psoriasis. The child died of congenital syphilis at the age of five weeks.

Dr. HENRY ASHEY thought the infant might have succumbed not to syphilis but to a pseudo-syphilitic process of septic origin.

Dr. EDMUND CAUTLEY enquired whether there was any post-mortem evidence of syphilis in the infant.

Dr. GEO. A. SUTHERLAND could not accept the psoriasis present in the mother as pathognomonic of syphilis.

Dr. HUTTON, in reply, said the whole question resolved itself into one of possibilities and probabilities. Transmission in this case could not be demonstrated, but was highly probable.

Mr. R. W. MONSARRAT (Liverpool) read a note on two cases of

#### MENTINGITIS TREATED SURGICALLY BY DRAINAGE.

The results were fairly satisfactory. The choice of a route for drainage was discussed.

Dr. EDMUND CAUTLEY dwelt upon the initial difficulty of distinguishing between simple bacic and tuberculous meningitis. In his own cases the result of surgical interference had been uniformly unfavourable.

Dr. J. R. LOGAN mentioned a case of chronic hydrocephalus where the lateral ventricle had been drained, but the child died some months later.

Mr. DAMER HARRISON had passed chromicised gut into the lateral ventricles for the purpose of draining fluid into the base, but he was not inclined to proceed with the operation.

Mr. MONSARRAT, in reply, thought no operation satisfactory that did not combine ventricular drainage with drainage of the subarachnoid space.

Dr. JOHN H. BRYANT read notes of a case of pneumococcal peritonitis, which he had observed in a girl, *æt.* 4½ years. The abdomen was opened, general acute peritonitis was found, and pneumococci were demonstrated in the effusion. At the autopsy there was no pneumonia or pericarditis, but pleurisy and peritonitis were present. Dr. Bryant was inclined to think that so-called idiopathic peritonitis was of pneumococcal origin.

Dr. JAMES BARR discussed general infection with the pneumococcus as shown by pneumonia, pleurisy, peritonitis, and meningitis.

The following communications were taken as read:—

(1) Mr. E. Clement Lucas: "Removal of a Nail from the Second Portion of the Duodenum."

(2) Dr. John McCaw (Belfast): "Notes of a Case of Infantile Scurvy."

(3) Dr. C. J. Macalister (Liverpool): "Observations on Cirrhosis of the Liver and Endocarditis in Children."

(4) Dr. James Carmichael: "Bimanual Examination in the Diagnosis of Abdominal Disease in Children."

#### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD JULY 5TH, 1901.

The President, Mr. G. ANDERSON CRITCHETT, F.R.C.S., in the Chair.

Mr. SIMEON SNELL (Sheffield) related a case of

#### BLINDNESS RESULTING FROM SODIUM SALICYLATE.

The patient, a girl, suffered from acute articular rheumatism, for which sodium salicylate was prescribed. She woke from sleep at 7.30 a.m. and said that everything was dark in front of her. On the medical attendant's visit between 11 and 12 he found her unable to distinguish between light and dark. The next day Mr. Snell saw her and found her perfectly blind. The ophthalmoscope disclosed nothing abnormal in either fundus. The following day he again saw her, when she was succumbing to pericarditis with endocarditis. Again nothing abnormal in either fundus was detected. There was no return of vision, and she died that same evening. It was calculated that the total quantity of sodium salicylate taken must have been at least 140 grains in sixty hours. Mr. Snell said he thought that there could be very little question that the sodium salicylate was the cause of blindness in this instance.

Mr. J. B. LAWFORD reported a case of

#### MELANOTIC SARCOMA OF THE CONJUNCTIVA.

The patient, a woman, was shown at the Society in June, 1896. In July following two pinkish nodules appeared on the conjunctiva. A month later the cornea became hazy, and the intraocular tension raised. In October, 1896, the eyeball and conjunctiva were removed and were examined by Mr. Devereux Marshall, who reported the growth to be a pigmented sarcoma. The pinkish nodules consisted of connective tissue, cells, and blood-vessels. There was no growth whatever within the eyeball. In May, 1897, the patient had a serious illness with brain symptoms, and it was thought that an intracranial growth was present. However, she got better. In October, 1897, some new growth was seen in the orbit, and the general health was not good. On October 21st, 1897, the growth was removed, and was examined and found to be a sarcoma. In August, 1898, another recurrence was seen. On September 1st, 1898, the growth was removed and examined by Dr. Jenner and found to be a sarcoma. In April, 1899, another pigmented spot was seen, and in the following September another had appeared in the upper lid. On September 14th, 1899, the whole contents of the orbit were removed. On March 20th, 1900, the patient was very ill and died on April 23th, but no necropsy was obtained. Owing to the patient's very irregular attendance and also to her refusing operation in the early stage of the disease her chances of cure were much diminished.

Major H. HERBERT, I.M.S. (Bombay), described "Conjunctival Bridges and Pouches," due to union of retrotarsal folds, a condition found in nine upper lids of seven patients of all ages. One or more retrotarsal folds had contracted permanent adhesions with the tarsal conjunctiva evidently while displaced downwards through swelling in some previous inflammatory attack. The adhesions were sometimes multiple along the summit of the one fold; in other cases smaller adhesions of underlying folds were found beneath the principal ones. The folds had retracted, except when held by the adhesions, thus leaving the permanently displaced portions as broad or narrow bands, or bridges of conjunctiva connecting tarsus and fornix and freely admitting the passage of a probe beneath them. There was no history of injury in any case, but in the majority there was or had been trachoma. Two cases were also mentioned in which small bridges of union had formed between folds in the lower fornix. In another patient recovering from acute conjunctivitis (membranous or pseudo-membranous) the actual formation of these adhesions was seen. The union was primarily by means of fibrinous exudation, which apparently became organised. Finally, another upper lid was mentioned in which a broad fold came down over the tarsus and had adhesions not only at its summit but also over the greater part of its surface, leaving only a shallow pouch or pocket under each curved lateral margin.

Mr. SYDNEY STEPHENSON communicated notes of a case of

#### MILD SYMPATHETIC IRIDO-CYCLITIS

in a child fifty-four days after removal of an injured eye. The interval between the original injury and the enucleation of the eye was twenty days. The injured eye was affected with puro-plastic cyclitis, but micro-organisms could not be recognised. The patient when seen 16½ months after the accident had made a complete recovery.

The PRESIDENT referred to an observation of Liebricht that pressure on the nerve stump in the vacant orbit was painful in these cases.

Mr. DEVEREUX MARSHALL asked Mr. Stephenson if this was a record case. He himself had seen a mild case develop between two and three weeks after an eye had been removed for injury, but he had never seen a case develop so long as fifty-four days after enucleation.

Mr. SIMEON SNELL narrated a case of recovery of both eyes under similar circumstances. Enucleation sometimes sacrificed the better eye of the two.

Mr. STEPHENSON, in reply, said that he was not certain

what was the longest interval observed, but he did not think that his was the longest on record.

The following cases and card specimens were shown:—

Mr. C. Wray: Gumma of the Orbit which occurred forty years after Primary Syphilitic Infection.

Dr. W. C. Rockliffe: Cystic Growth of the Retina (probably Carcinoma) Secondary to a Primary Scirrhous of the Breast. There was evidence of both eyes being affected.

Mr. Marcus Gunn: Exceptional Appearance of a Choroidal Lesion, probably tuberculous.

Mr. Inglis Taylor: Peculiar form of Vitreous Opacity.

Mr. Harman: Hole in the Macula.

## France.

PARIS, July 14th, 1901.

### PUERPERAL INFECTION.

At the Académie de Médecine M. Budin spoke on the treatment of puerperal infection as practiced by him for the last ten years. If fever set in, in a woman recently delivered, and that at the same time clots, fetid or not, were found in the uterus, interference might be limited to removal of the clots and washing out of the uterine cavity. But if the mucous membrane were found to be diseased, especially at the point of insertion of the placenta, the physician should not hesitate to practice curettage of the organ. Rapid improvement followed, provided that the operation was not retarded; but when the infection had lasted already several days a cure was effected more slowly, as the toxic germs had penetrated into the economy.

On the other hand, where the woman was delivered or had aborted several days after the rupture of the membranes, if the amniotic liquid were fetid, the same treatment applied.

### THE THERAPEUTICS OF LECITHINE.

M. Lancereaux treated the question of the employment of lecithine in therapeutics. Recent researches have proved that lecithine plays an important rôle in the nutrition of the organism in general, and the nervous system in particular. Several experiments have confirmed this fact, and have demonstrated, moreover, an increase of weight of the animal or of man under the influence of the agent. Professor Lancereaux instanced the cases of two patients in his wards who were suffering from pancreatic diabetes arrived at an advanced stage, and who wasted away in spite of every effort to prevent the emaciation. Under the influence of lecithine not only did the wasting cease but the patients gained rapidly in weight and at the same time their general condition was improved.

These results prove the great value of lecithine as a stimulant of nutrition. Not only does it arrest the rapid denutrition of diabetic patients which generally nothing arrests and leads to phthisis, but it increases their weight, restoring to them their strength, and, to a certain degree, their buoyant spirits.

He also employed lecithine in several other cases, in persons suffering from different affections accompanied by denutrition, and the results were always the same, an increase in the weight and a rapid progression of strength. A young man suffering from osseous tuberculosis with amyloid kidneys and abundant albuminuria, was given six grains daily of lecithine for fifteen days; his weight increased by six pounds. A child,

set 10, extremely thin and ill-nourished, with coughing and hectic fever every evening, was ordered four grains of lecithine daily; at the end of a month he had gained four pounds in weight, while the general condition was notably improved. A little girl, set 8, ill with bronchopneumonia and in a very wasted condition was given the same dose of lecithine for a month with similar results. Other examples might be cited, but these are sufficient to establish the excellent effects of lecithine in all cases of rapid denutrition.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 13th, 1901.

At the Society fur Innere Medizin, among those who took part in the discussion on

### TUBERCULOSIS

were A. Fraenkel and v. Leyden. The former said that he had made extensive investigation into the presence of bacteria in the blood, and it was indubitable that the presence of bacteria in living blood was not incompatible with maintenance of life for lengthened periods. The pneumococcus had been observed in blood for six months. The speaker would not deny mixed infection, but he would not ascribe every possible thing to this origin, and especially failures in treatment. The fever was not always due to it; tuberculin inoculation showed that. In a recent investigation in the last stage of the disease in a patient no bacteria were found in the blood. How could they attribute the hectic fever to this vanishing quantity of germs? It was undoubtedly the product of the toxins formed in the cavities. The significance of germs in the blood depended on their numbers. In fibrinous pneumonia the pneumococcus only was constantly found. If present in large quantities it might be taken that death would result from sepsis or that metastases would form, but with a small number of germs their presence was of no importance. The majority of these patients got well, whilst experiments on animals proved that the bacteria were virulent.

Hr. v. Leyden said that Hr. Kaminer had brought forward an important practical question, one, moreover, that could not be solved at once. He had long been interested in the subject of the artificial interruption of pregnancy. In 1891 he had discussed the question of pregnancy and heart disease, as to whether artificially induced abortion should be performed. Gynecologists had espoused different views as to his proposals. Gussnerow had at first opposed them, but later on had conceded that in bad cases of cardiac disease the pregnancy should be interrupted. In connection with his work he had suggested artificial abortion in renal disease and phthisis. In his view the question should be decided on its merits in respect of each case, and not on general lines. The old belief that tuberculosis came to a standstill during pregnancy, and got rapidly worse after delivery, could not be retained, one could not see how pregnancy could be a protection against tuberculosis. Formerly it was a custom to starve lying-in women for a week after delivery, and this perhaps contributed to the more rapid decline, much would depend on the state of the woman, and if she was living in great misery she should be freed from her burden. In any case the physician had the right of interrupting a pregnancy, a right which formerly, in view of the destruction of infant life, had not been con-

ceded. Another question was, should the physician dissuade tuberculous people from marrying. Here also no distinct principle could be laid down, as the transference of the disease to the embryo not having been decisively proved.

At the Berlin Medical Society Hr. Herzfeld showed a  
CASE OF RECOVERY AFTER ABSCESS IN THE LEFT  
FRONTAL LOBE

in a young man, *æt.* 20. The patient came to the Klinik on May 15th; he had nasal catarrh first on the right and then for three weeks on the left side, then he had severe left frontal headache of a malarial type. Examination showed swelling of the mucous covering of the turbinated bones, copious purulent discharge, high temperature (40 C.), and slow pulse, 86 at first, later 50. The speaker, from the character of the pulse, concluded that intracranial disease was present. On May 22nd he trepanned the left frontal sinus, this contained much pus and granulations. The posterior wall of the sinus was carious, and could be penetrated with a probe. This was removed when the dura mater projected. No pus appeared at first. Then a piece of frontal bone was opened, the dura mater split, when a large quantity of pus escaped from the sub-dural space. A small fistula led into the abscess cavity proper. This was enlarged until the finger could be passed in. The result was favourable. The rather large intra-dural and intra-cerebral abscess had caused absolutely no other symptoms than those named. The intelligence had in no way suffered except for slight weakness of thought.

Hr. Gluck showed four children with

RECURRING TUBERCULOUS PERITONITIS, in which puncture, laparotomy, &c., had been performed without success. Recovery was brought about by leaving the abdomen open, on several occasions in two sittings he had opened it widely, with a transverse incision added, and had removed the tuberculous mass partly with the blunt spoon, had resected the omentum, and packed the abdominal cavity. The duration of the recovery after the operation had been from four to one and a-half years. During the after treatment one could watch the caseous masses gradually disappearing, to be first followed by fungous granulations and cicatrisation.

The *Deut. Med. Zeit.*, 53/01, relates a case of

TRIPLET ABORTION IN TWO STAGES.

A woman, *æt.* 30, after two months suppression, had hæmorrhage, and was delivered of a two months' fetus. Three months later she again complained of pain, and stated that the abdomen had continued to enlarge after the last abortion, and that the menses had not returned. On examination a pregnancy of four or five months was diagnosed. Soon after this, on lifting a heavy weight, bleeding came on again, and two living fetuses, both males, were expelled, one being 24 *ctm.* in length, the second 21 *ctm.* They had a common placenta.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 13th, 1901.

CECHISCH CONGRESS.

THIS is the third Congress held under the auspices of

this body, although it has been in existence for the last twenty years. Its object is the furtherance of medicine and allied physics among the Cechs and Slavs whose language is official. It is now nineteen years since the last Congress was held, which is a very unusual interval. On that occasion the inauguration took place of a Cechisch University at Prague, which is now a flourishing rival to the German seat of learning in the same city. The numbers present at the Prague meeting are computed at 1,000, while the XII. sections had 360 papers read of a national interest. It was suggested as an explanation that the last time they met, it was to obtain a charter for a University; on the present occasion a second University is proposed on account of the rapid increase of students at the first. The second University will be for Moravia, with the native language, which they consider is more conducive to education and scientific investigation, the promoters pointing to Holland and Sweden for examples.

Prof. Thomayer opened the proceedings with an exhaustive paper on "The Influence of Civilisation on the Nerve System." He treated the subject in a manner that proved that civilisation was not injurious to the nerve system, but rather favoured its preservation. On the last day Prof. Bayman gave a very interesting address on the advance of chemistry and its influence on physics.

The next Congress is fixed for 1906 in the same city.

### MYELITIS CHRONICA.

At the Bohemian Society of Medicine Prochazka exhibited two cases of a neurotic order. The first was that of a young man, *æt.* 29, a porcelain painter, who complained of general weakness in the lower extremities which had commenced about five years ago, otherwise he was fairly well. On examination the objective symptoms were distinctly marked paresis of the lower extremities, pyretic movement, and distinctly spæstic symptoms. There were well-marked muscular tonus, forcible resistance to passive movements, increased patellar reflex, shortening of the Achillis tendon, and pes equinus of the feet. Sensibility was normal, bowels regular, but the function of the bladder was disturbed as the feeling of micturition brought about instant attention, the patient having no power to retain his urine. The upper extremities had the triceps reflex increased. There was no history of syphilis, chronic hydrocephalus, or cerebral diplegia, as no cerebral symptoms were present. The bladder disturbance seemed to be the only differential point between multiple sclerosis and chronic myelitis, which is common in the latter.

The second case was that of a man, *æt.* 30, who for twelve years past had suffered from a distinct weakness in the lower extremities, which he observed in springing or jumping. A similar sensation was also present in the hands. The leg weakness had increased within the last four years more rapidly, he having to assist himself with a stick in locomotion. The first symptom of pain appeared two years ago in the form of cramp while shooting or undressing. For the last ten years the hands had got thinner and the muscular tissue wasted. The object of examination pointed to hydrocephalus nystactiform contractions, atrophy of both optic nerves, atrophy of the muscles of the hands of the Aran-Duchenne type, atrophy of the muscles of the lower limbs, analgesia over the whole trunk,

thermo-hyperæsthesia in the extremities, although the patient is able to tell the difference between hot and cold water, he is unable to distinguish smaller differences of temperature. There were also spastic symptoms present, with exalted muscular tonus, cramping in the quadriceps cruris when active movement was produced, as well as fibrillary contractions in the upper limbs.

Proczakka diagnosed disseminated sclerosis in this case. Syringo-mylitis was negatived by the long duration (sixteen to eighteen years) of the disease, the temperature sensation, and the absence of trophic disturbances. Amyotrophic lateral sclerosis was also negatived by the protracted duration of the disease.

#### BLOOD PRESSURE IN FEVERS.

Federn read an exhaustive paper on blood pressure to the "Gesellschaft," which has much interest for the medical practitioner in the application of drugs. Scarlatina, cholera, and malaria, as he has told us before, have always a high blood pressure, and in scarlatina the higher the pressure the more severe the attack, probably owing to the early cardiac hypertrophy not being maintained.

On the other hand, influenza can be diagnosed by the low blood pressure being 50 to 60 mm. of mercury, or 1.9 to 2.36 inches. Eight years ago he pointed this out from the intestinal symptom which seemed to point to dilatation of the vessels of the bowel. The only other disease that might be confounded with this low pressure is icterus, which may be differentiated by the colour of the skin, conjunctiva, &c.

In the recent epidemics of influenza, antipyrin, phenacetin, salipyrin, &c., were used as specifics, which looks rather anomalous when we consider that it relieves the pain in febrile or non-febrile conditions, and that these drugs are supposed to act through their depression of the arterial system. The curative action of these drugs in influenza rests on the physiological fact that they dilate the small arterial vessels, which are greatly constricted by the influenzal toxin, and thus diminish the resistance to the cardiac efforts, which are also weakened by the toxin. The first effect of the influenzal poison is expended on the heart and vascular circulation, giving rise to a multiplicity of symptoms such as fatigue, headache, &c., and according to the severity or otherwise of the hæmatic symptom some patients suffer from a variety of symptoms not met with in others, such as brain affections, others from muscular troubles, while a third may have only a bowel lesion.

The primary cause is the toxin, as the simple interference with the cardiac movement would not so affect the muscles, while the slow recovery from the bradycardia, often lasting a year, confirms this opinion.

The prognosis in disease can also be gauged by the blood pressure with approximate accuracy. In diseases of high pressure the danger is greatest in elderly people, and when not fatal may so irritate the vasomotor centres as to produce arterio-sclerosis. It has been affirmed that the opposite condition produces calcification of the vessels, but this is incorrect, although normal blood pressure not infrequently produces arterio-sclerosis.

The treatment of influenza is correctly carried out with antineuralgics and antipyretics in order to relieve the blood pressure. Purgatives also relieve the atony of the bowel.

Eisenschnitz thought the influenza poison damaged

more than the heart, and opined to show that it was a case of general intoxication.

Teleky objected to antineuralgics as specifics in influenza, and doubted very much the action ascribed to the heart.

Winternitz asked if the blood pressure remained low throughout the disease, or was it altered in the event of croupous pneumonia appearing. As to arterio-sclerosis, he always understood this to be associated with high pressure, which so paralysed the vascular system as to induce the sclerosis.

## The Operating Theatres.

### MIDDLESEX HOSPITAL.

#### LAPAROTOMY FOR PERITONITIS OF DOUBTFUL ORIGIN.

—Mr. JOHN MURRAY operated on a man, æt. 33, a cab driver, who had been admitted for abdominal pain. The man had had good health all his life, but he stated he had suffered from indigestion. A fortnight before admission he began to complain of pain across the lower part of the abdomen. The pain was of a gripping character, and he was unable to account for it in any way. It got worse, and he was obliged to take to bed. He felt very weak, had no appetite, and during the attacks of pain he could feel a lump in the left iliac region about the size of a walnut; the abdomen was very tender and deep inspiration caused pain. His bowels were confined, and he had great difficulty in passing very scanty motions. He was ordered an enema, which produced a good evacuation, and he passed a large quantity of flatus. The day before admission he vomited once, the vomited matter being white in colour and frothy. The pain commenced always on the left side of the abdomen. On admission at 10 p.m. he was a well-nourished man with a great deal of tenderness in the abdomen. He lay on his back, the face was pale, he was not collapsed, the skin was moist; the abdomen was slightly distended, the abdominal wall rigid, and respiratory movements were limited to the upper part. The abdomen was resonant except in the left iliac region, where there was marked dulness extending into the left flank; liver dulness was normal; there was resonance in the right iliac region, and nothing abnormal could be felt on deep palpation. There was marked tenderness over the whole of the abdomen, especially in the left iliac region, where an increased sense of resistance was distinctly felt. The temperature was normal, pulse 98, the tongue was moist and thickly coated with white fur. Examination per rectum the bowel was found to contain some hard fæcal matter, but nothing abnormal could be felt either in the rectum or in the pelvis. On the following day the patient's condition was worse, the pain and tenderness were more marked, the rigidity of the abdominal wall more pronounced, the man had vomited once, the vomited matter being greenish in colour. The bowels had not acted satisfactorily, though he had been ordered an enema only a few scybalous masses came away; pulse was 112, temperature 101°. It was decided to open the abdomen, the patient's condition being obviously serious. An incision was made in the middle line below the umbilicus. On opening the peritoneum a quantity of stinking, purulent fluid escaped; the intestines were everywhere

adherent and covered with numerous flakes of thick yellow lymph. The abdominal cavity was flushed out with sterilised water at temperature of 110°, and an attempt was made to find the source of infection. The cæcum and appendix were found to be normal; in the left lumbar and iliac regions there was a large, hard mass consisting of matted coils of intestine, and on separating some of these adherent coils a large collection of exceedingly fetid pus was evacuated from the left iliac fossa. At this stage of the operation the patient stopped breathing, but soon recovered on artificial respiration being performed. As it was not considered desirable to further investigate the cause of the trouble, the abdomen was mopped out, a glass drainage tube inserted into the pelvis, and the wound closed with silk-worm gut sutures passed through the whole thickness of the abdominal wall. Mr. Murray said that the interest of the case lay in the diagnosis, which was rendered difficult on account of the impossibility of obtaining anything like a complete history from the patient. When seen shortly after admission, he (Mr. Murray) was of opinion that the case was not one of peritonitis, and was rather inclined to regard the symptoms as due to chronic intestinal obstruction; the general appearance of the patient and the normal temperature rather strengthened this view. The pain was of distinctly colicky character, and during attacks the patient was seen to raise himself in bed on his hands and knees, which was thought not likely to occur in peritonitis. The case had none of the features of an ordinary one of appendicitis; if the patient's statements were to be relied on his symptoms commenced and for some time were limited to the left side of the abdomen, and the tenderness was less marked on the right side, and there was nothing to be felt in the region of the cæcum. There was no history of injury such as might point to a rupture of the intestine, and although the man complained of attacks of indigestion, there was nothing to indicate perforation of a gastric or duodenal ulcer. Operation was therefore postponed, the patient being ordered an enema and a hypodermic injection of morphia. On the following day there could be no doubt that the patient had general peritonitis, though there was nothing to indicate the cause of the condition; therefore it was decided to operate at once. The abdomen was opened in the middle line, as it afforded the best position for exploring all parts. All that could be determined at the operation was that the origin of the infection lay in the matted coils of intestine on the left side the exact nature of which was purely speculative, though Mr. Murray thought that it might be accounted for by some slight injury which had produced rupture of the intestine, which had escaped the patient's recollection, or that it was secondary to ulceration of the intestine with perforation. He pointed out that from the condition found at the operation it obviously would have been better to have opened the abdomen the night before, though it would not have made any difference to the ultimate result, as the extensive adhesions present showed that the peritonitis was at all events of some days' duration, if not dating back from the commencement of the illness a fortnight before, and such a condition he considered absolutely hopeless.

The patient died twenty-four hours after the operation. At the post-mortem an annular growth of the

upper part of the rectum was found giving rise to considerable stricture, with ulceration and perforation at seat of growth; there was general peritonitis. The glands of the mesentery in the region of the growth were infiltrated, otherwise there were no secondary deposits.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 17, 1901.

### LORD ROSEBERY ON A NOBLE PROFESSION.

It would be hard to find a more fitting orator than Lord Rosebery for any festival requiring cheery wit and a philosophic knowledge of men and things. Last week he occupied the chair at the twenty-eighth festival of the Royal Medical Benevolent College at Epsom, of which institution he is President. The college is one of the few organisations in existence for the benefit of the families of deceased medical men. Its present position was tersely described by Lord Rosebery when he stated that there were fifty foundation scholars, chiefly necessitous orphans of medical men, and the fixed income of the institution was not more than one-third of the £6,000 which had to be raised for its maintenance. It is gratifying to be able to announce that the result of the appeal made by the noble chairman resulted in subscriptions and donations to the extent of £4,127. The mere fact of the necessity of such a step implies that the members of the medical profession have not extended to Epsom College that measure of support which it deserves at their hands. The well-to-do medical men in the United Kingdom could readily support the Epsom foundation in affluence by an individually small contribution. It is a melancholy fact that the conditions of practice in this country are such that in many cases the medical practitioner is unable to make any provision for his wife and family. Should he die before the children are grown up and equipped to take their part in the battle of

life their lot is often of the hardest. The Chairman summed up the position in a few terse and eloquent sentences when he remarked that it was easy in an assembly like that he was addressing to fancy that the medical profession was nothing but a brilliant and a lucrative one, but when one came to think that there were some thousands of medical graduates turned out every year—that there were some 30,000 in the United Kingdom—one could not feel but that the number of blanks in that profession must be out of all proportion to the prizes. The princes and the prizemen formed only a small proportion of the great number in the country, and of the small practitioners in the towns who are at the beck and call of disease and suffering by day and by night, in every weather and at every hour. It was a noble profession, but in many cases it was a profession of forlorn hopes. The truth of that presentment must be at once endorsed by all who know the inner life of the medical world. The interests of the medical profession are at the mercy of unfair competition on all sides. Perhaps when Lord Rosebery returns to Office in the Government, as one day he assuredly will, he may remember the sad case of the medical profession and help forward some saving legislation on its behalf. An amended Medical Act is wanted as an initial step whereby quack practice might be readily and efficiently repressed; the patent medicine stamp should be abolished; but, above all things, a General Medical Council should be constituted upon a basis really representative of the rank and file of the medical profession, and its powers should be extended so as to include the power of protecting the public as well as the profession from illegal practice. In that way Lord Rosebery might do much to relieve the forlorn hopes of what he has kindly spoken of as “one of the noblest, if not the noblest, of all the professions.” It is to be hoped that the hurry and rush of political life, especially for those who are weighted by the responsibility of office, will not obliterate or overwhelm the convictions that were stated by him with so much eloquence at the recent festival. As everyone knows, it is one thing to give utterance at a public dinner to abstract and general admissions of the existence of an undesirable state of affairs, but quite another thing to undertake the task of practical reform. It seems hardly possible to imagine that the Medical Acts will remain untouched when Parliament finds time to turn to the many social matters that demand earnest attention. Meantime it is the duty of the medical profession to proclaim its wants with clearness and steady insistence, and to urge that the public speeches of statesmen may be backed up with legislative performance.

#### THE CASH VALUE OF A FINGER.

A PROVISION merchant by ill-chance happened to scratch the second finger of his right hand on a nail projecting from some part of a haddock box. On April 14th, 1900, he consulted his private medical

attendant, in Leith, five days after the accident. The physician *prescribed* (according to reports of the case) for him. On May 18th the digit had to be amputated; *i.e.*, thirty-nine days after the scratch. The merchant then claimed £500 damages from his physician for professional negligence. The judge who first heard the case in the Lower Court dismissed the action, but on appeal the Higher Court decided that there were grounds for it going to trial. Before this, however, the defendant settled the case by payment of £100 and expenses. As reported the important facts in the case *non sunt*. The doctor explained that his work after his first interview with the pursuer had had to be delegated to another physician, owing to his own ill-health. No note is given of how the pursuer acted up to instructions, if he committed indiscretions, &c. An instance of personal application might well be noticed here. The writer was summoned to a club official, the greater part of the top of whose left index finger hung by only a narrow band of skin to the proximal portion of the digit; the nail crushed and crumpled, but the terminal phalangeal bone only bruised, not broken. These injuries were due to a crush between a door and its jamb. The detached portion was pulseless, insensible, bloodless; the terminal phalanx devoid of periosteum over a part of its surface. The method of treatment followed consisted in trusting to nature. The various bits brought together after their surfaces had been “dabbed” only with 1:40 carbolic, covered with protective, protected with dry antiseptic cotton wool in excess, and the hand and arm supported by a sling. The questions at issue were mainly: “Is it possible to preserve the vitality of the bruised and torn fragments? Which is of greater importance: Rendering the wound aseptic, or endangering the vitality of the half-separated portions by the use of antiseptic agents?” Now, if this incomplete and theoretically inefficient cleansing of the wound had been followed by septic conditions, the judgment of the exponents of legal empiricism would probably go against the adviser of such a plan of treatment. If successful, as was the case just mentioned, no fault would be found although the measures adopted in each event were the same. It is most common to meet with instances among doctors in which a finger, or part thereof, has had to be amputated owing to their too faithful adherence to antiseptic rules, to the death of tissue caused by too forcible bactericidal measures, and ignorance of the fact that antiseptic agents employed in even slightly too concentrated a form may kill more than bacteria, and result in more harm than benefit. Each case of crushed or poisoned fingers or toes differs in character and detail. The result in such cases physicians or surgeons must needs strive for, consists in the attempt to save tissue. If vitality be so low that the action of antiseptics will possibly destroy the diseased or injured part, trusting to nature may be quite successful. Should this fail, the

end is one and the same—the knife. How, then, can anyone judge, especially in the absence of emergency, the motives which may lead to the adoption of one of two courses, when it is apparent that either of them may fail, either may succeed, either seem to be unsuitable, or either to be warranted? Cases belonging to this category usually impose most unmerited hardships upon medical men. How can they explain that they prefer expectant methods, and have obtained good results from them, to the more official, up-to-date measures, in dealing with certain cases? This argument is logical, full of common sense; the chances of continuance of vitality in severely affected tissues, when reliance is chiefly placed upon the recuperative powers of nature, are often better than after a routine application of antiseptics from a too conscientious regard for the fashionable usages of the day.

#### NEW DEPARTURE IN PENALISING THE PROFESSION.

SIR FORTESCUE FLANNERY, M.P., has the reputation of being a level-headed and capable man of business. What Nemesis, then, can have driven him to bring forward the fresh clause of which he has given notice as an amendment to the Factory and Workshop Acts Amendment Bill, now being discussed by the Standing Committee on Trade of the House of Commons? We cannot persuade ourselves that Sir Fortescue Flannery could have drafted the clause himself. For not only is it utterly objectionable in principle and design, but it betrays such crass ignorance in every line, and is withal so entirely unworkable, that we can only imagine the clause was drafted by some illiterate and ignorant persons, and that they in an evil hour have been able to exercise pressure to induce Sir Fortescue to adopt it without his having even read it. The clause in question is another of those unjust inroads on the personal liberty of medical men whereby government by special penal legislation exacts the fruits of their scientific knowledge and experience. Such forced labour is indistinguishable from slavery, and whether paid for or not is utterly objectionable and unjustifiable. In this case Sir F. Flannery does not even propose to gild the chains of the forced labourers, and he proposes not even the noble half-crown for the important services which, in his ignorance of the subject, he hopes to compel medical men to render to the public. It may not be inopportune to ask whether he allows the Government to compel him to give information on special engineering subjects to the public, and if he is content to do such work for nothing? By his proposed new clause he would compel medical men, attending a case of "anthrax (suspected)," to take some of "the serum" from the patient, whether the latter or his friends are willing or not, and to send it to "a bacteriological expert" for microscopical examination; and in case of the death of the patient some person or other, for

no one is specified, is to take "the serum" from the dead body and forward it to the same destination. It is somewhat amusing to note that what "the serum" means is not indicated. It is well to be outspoken on such a matter. To us the proposal is nothing short of an outrage on the patient and his friends, to say nothing of the medical attendant who may consider the proceeding would seriously affect a prostrate sufferer from anthrax, for we know well the alarm with which most persons, especially the poor and ignorant, regard anything which their imagination suggests is in the nature of what they all term "an operation." Is the doctor to be compelled to waste the flickering energy of his prostrate and dying patient by arguments directed to prove the painlessness and harmlessness of the proceeding, and the benefit to science, and the evidence which it may afford in legal proceedings against an employer? Even if the doctor thought the agitation of this proceeding might injure or kill his patient, under Sir F. Flannery's clause he must persist in drawing the serum. The idea is repulsive in the extreme. It is more cruel than the most reckless experiment in vivisection, and it is not certain that the medical attendant would not be liable for cruelty were he to carry out such a heartless and unjustifiable experiment, and the offensive proposal has not even the recommendation that it is intended for the relief of the sufferer. He would receive no benefit from it whatever. When we add that even if the medical attendant succeeded in overcoming the objections of the friends and the patient, the whole heartless proceeding would in most cases be utterly useless, we shall have completed the indictment against this most unjustifiable proposal. Now, it is well known to all persons acquainted with the subject, but obviously not to Sir F. Flannery, M.P., though he represents a district where anthrax is familiar, that the bacilli are very rarely indeed to be found in the blood in the early stage of anthrax, by microscopical examination, even when the presence of the virus can be demonstrated by inoculation. The negative result would tend to seriously confuse the diagnosis in the opinion of many persons. The action of Sir F. Flannery, M.P., in persisting in putting forward this proposal is greatly aggravated by the fact that the Home Office refused to act on the suggestion to insert the clause in the Bill, on the irresistible ground that existing powers are quite sufficient to enable all necessary information about such cases to be obtained. We trust the whole profession, and all reasonable men will rise against this indefensible proposal to impose fresh penal legislation on medical men, and to compel them to inflict unjustifiable hardship, pain, and cruelty on their patients. The following is the text of the proposed clause, and never did so few words construct such a monument of ignorance and folly.

*Sir Fortescue Flannery's Proposed New Clause in the Factory and Workshop Acts Amendment Bill.*

"With every notification by a doctor (1) or other

interested person of a case of anthrax (suspected) <sup>(2)</sup> poisoning, the medical practitioner attending <sup>(3)</sup> the patient shall immediately forward a specimen of the serum <sup>(4)</sup> to a bacteriological expert appointed by the Secretary of State for microscopical examination <sup>(5)</sup>, and in each fatal case of anthrax a specimen of the serum taken <sup>(6)</sup> as soon as possible after death, shall also be forwarded to such expert by the doctor who certifies the death." <sup>(7)</sup>

The following points are deserving of attention:—

(1) Doctor of what? Music, laws?

(2) Merely "suspected" cases are not notified.

(3) If some "other interested person" has sent away the notification without informing the doctor, how can the latter be compelled to send the serum along with it?

(4) What serum? Who is to take "the serum"? There must be no blood with "the serum"!

(5) Such microscopical examination in early stages usually gives a negative result, and this may lead to a denial of the case being anthrax.

(6) Taken by whom? Who has authority to forcibly make such a post-mortem examination?

(7) What is to happen when the bacteriological expert has made his microscopical examination? To whom is he to report his results?

(8) Inquests are usually held on fatal cases of anthrax. Interference with the body before the inquest would cause serious difficulties with the coroner.

## Notes on Current Topics.

### Cocainisation of the Spinal Cord.

At the meeting of the "Société de Biologie," on the 25th ultimo, a very interesting discussion on the action of cocaine as anæsthetic and the best method of cocainisation of the spinal cord took place. To exhibit the constricting power of the drug M. Laborde exhibited a rabbit, the sympathetic nerves of whose ears he had cut. The vessels of the ears became enormously engorged, and then he hypodermically injected five milligrammes of cocaine into the base of the ear, which quickly became exsanguine. This effect M. Laborde considers is not wholly due to the effect of the cocaine on the muscle tissue, but is due in great part to its effect on the nervous tissue. And he considers that the direct action of the drug on nervous tissue is a great source of danger, and quotes the case of a woman in whom a carelessly-given interspinal injection produced dangerous effects from coming in contact with the nerve tissue. For the intra-medullary injection he proposes an extra-dural one, where absorption is very rapid. Indeed, he found that intermuscular injection was in many cases equally useful. He gave hypodermic injections to dogs of from five milligrammes to one centigramme to animals of from four to five kilogrammes in weight, and found that complete anæsthesia of the posterior limbs down to the very footpads followed. M. Brocard, who adopted the extra-dural method, found that in sixteen cases a half per cent. solution produced relief from pain in sixteen cases of sciatica, one of herpes zoster, one of lumbago, and one of "lightning pains" in the limbs. No unpleasant effects followed, with the exception of

one case, a neurasthenic patient, who complained of headache after the anæsthetic effects had passed away. The pain in every case was relieved within two or three minutes after the injection, and in the cases of sciatica the freedom from pain continued for four days, in some cases, and for two days, at least, in all. The members appear to be agreed that the tolerance of the epidural cavity of the spinal canal is underestimated. M. Brocard injected with impunity 1,000 grammes of serum into the epidural cavity of a dog seven kilogrammes in weight without producing any symptoms of compression. But a profuse polyuria, lasting for some hours, followed. By injecting a dark-coloured liquid into the space, he demonstrated clearly at the autopsy of the animal the rapidity with which absorption takes place in the part. Any modification of the interspinal operation of cocainisation that diminishes its risk will be welcomed by every branch of the medical profession. Cocainisation of the cord, if robbed of its risks, offers to displace all the other methods of anæsthesia in minor surgery. M. Laborde's proposal for extra-dural injection seems a step in the right direction, but it will require considerable skill and practice to acquire the necessary dexterity of manipulation to avoid piercing the membrane and yet inject the canal.

### The Assumption of False Designations.

WITHIN the past few days two persons arrested by the police described themselves as members of the medical profession, and a third, who was found to have beaten a poor woman savagely over the head with a stick, without provocation, declared he was a medical student. He may possibly have commenced qualifying studies and his name be enrolled on the *Students' Register*. For the honour of medicine we hope it is not, but if it should be we hope it will be struck off. The leaven of such men must be kept out of the profession if it is to retain the honoured place in public esteem it has so long enjoyed. But are the men who so often figure in police reports as doctors and medical students really what they pretend to be? In nine cases out of ten we have failed to verify the names on searching the official *Register*. The statement is apparently made to excite sympathy from a public that naturally esteems medical men as their best friends in sickness. The impostor trades on this. He shelters himself under the cloak of medicine, and would pass off his blackguardism and brutality as the innocent jocularity or frivolity of the medical student. The constable takes the description and carefully enters it in the station-book and the charge-sheet. The lie is again repeated before the police magistrate, and thus finds its way into the daily papers until many respectable members of society come to think that a large number of medical men and students are to be found as *habitués* of the police cells. This dirt-throwing on the medical profession should be

stopped. Our ranks are not recruited from "corner-boys," and no profession calls for greater sobriety of conduct from its members. It is intolerable that every ruffian found in a drunken row should bring discredit on the profession by a lie easy of detection—a lie told deliberately to excite a friendly feeling in the audience and take off somewhat from his richly-deserved punishment. In every police-court there should be a copy of the *Medical Register* and of the *Medical Students' Register*, and any person claiming to belong to the profession should be compelled to prove it; and this not in palliation, but rather as an aggravation of his crime. If it should so happen that a medical man or student be found to have committed a brutal offence, his name should be reported to the General Medical Council. It is imperative that medicine be kept free from all uncleanness; the man coming within her portals must have clean hands.

#### The Hospital "Scandal" at Stockport.

THE Town Council of Stockport appears to be unable to dispose of the charges of misconduct in the management of the Isolation Hospital. The matron of that institution has addressed a letter through her solicitors to the Council, pointing out that suggestions have been publicly made that she had starved the patients and staff for the sake of personal gain. Under these circumstances an independent public investigation was asked for, but declined by the Sanitary Committee on the ground that no useful purpose would be served by acceding to the request. The question was raised later in the Town Council and gave rise to an acrimonious and heated debate. It was stated that the stock of linen, utensils and other things was defective, and that one patient had to have vegetables and pudding on the same plate, whilst another had to wait until a plate was finished with by the occupant of the next bed. The Mayor of Stockport and other members of the Council appear to have objected strongly to any discussion of the matter, because of "holding up the town to notoriety" and to bring the place to disrepute. That standpoint certainly is not likely to commend itself to those who entertain a high ideal of the duties and responsibilities of local governing bodies. The Town Council may decline a public inquiry when demanded by a late official, but they surely can hardly hope to escape the much more public and searching ordeal of an inquiry by the Local Government Board. If the state of affairs at the Isolation Hospital has been anything like as bad as presented by rumour it is a wonder how the matter could have escaped the notice of the Board inspectors.

#### Plastic Operations on the Ureter.

FROM time to time there have been put forward fascinating proposals for the treatment of those cases where loss of substance has occurred in the ureter to such an extent that vesical grafting is not possible. Under these circumstances many methods have been advocated, but in the majority of them experience of

the results has been gained by experiments on animals. Nussbaum, in 1887, suggested joining the divided ends of the ureter by a connective tissue tube, but it must be urged against this suggestion that contraction would almost certainly follow. Rydygier, in 1892, improved on this idea and favoured the plan of constructing the splicing of the ureter from the skin of the abdominal wall. Van Hook has published an ingenious plan for replacing a lost portion of the ureter by means of a diverticulum when it is not possible to implant the duct directly into the bladder. A few years ago a very interesting report was published on the substitution of the upper portion of the ureter in a calf by a decalcified turkey's wing bone, the backflow due to intra-vesical pressure caused the failure of the investigation, but a perfect tube of connective tissue was reported to have formed round the bone. Dr. J. B. Bacon, of Chicago, recommended the substitution of the ureter, where it was wanting, by an isolated piece of bowel, and D'Urso and Favii, of Rome, suggested the Fallopian tube as a substitute in woman. Mr. Henry Morris has now given it as his opinion that it is more than improbable that these suggestions will be accepted by the surgeons of to-day, and he also considers that the condition of the patient under the circumstances in which plastic operation on the ureter is likely to be called for would not be such as to justify a trial of these procedures. Though the surgery of the ureter is young in years it has lately come prominently into notice, for since 1894 about 100 papers on the subject have appeared, whilst from 1890 to 1894 scarcely a dozen articles were published.

#### Police Station Medical Certificates.

SOME points of general interest to the profession have lately arisen at Newcastle in connection with the medical examination of persons charged with being drunk and incapable. Two cabmen in that undesirable position asked to see their own medical men, but in each case the police called in Dr. Baumgartner, who is presumably their official surgeon. The magistrate, Sir Charles Hamond, appears to have adopted the view that a request of the kind mentioned should have been granted. The police, he remarked, should always be very careful in agreeing to the demand of any person who wanted a doctor under such circumstances, because there were peculiarities in the life of every man, and he might readily believe he would be better examined by his own medical man than by a stranger. There is much sound reason in that view of the case, but the police are hardly likely to abandon their somewhat autocratic attitude in dealing with persons taken into custody upon a charge of drunkenness. There is much to be said in favour of a routine medical examination of every prisoner lodged in a police station on suspicion of intoxication. Another of the magistrate's suggestions may be accepted with little hesitation. He has firmly stated

that the opinion of the medical man called to the police station should be reduced to writing, in place of the verbal report at present often tendered to the police. The door to possible abuse thrown open by the slipshod method of statement by word of mouth is so obvious that it is a wonder any responsible magistracy could accept evidence of the kind.

#### Pathology at the London Hospital.

THE Hon. Sydney Holland struck a true note when he said that the new Pathological Institute at the London Hospital was a recognition of the responsibility which rests on the management of the largest hospital in England with its vast power of doing good and lessening misery and suffering, and with its equal power of doing mischief if it refuse to advance. Mr. Holland and his House Committee have realised that it was their duty to provide accommodation for men whose life is spent in the specialised work of investigating the exact cause of death by the scientific methods which the great advances in bacteriology, chemistry, and microscopy have placed at the disposal of modern observers. The number of post-mortems at the London Hospital is from 900 to 1,000 in a year, and in the new Pathological Institute such studies of the causes of disease can now be made under conditions which will secure success and make advance possible and probable. The inauguration of this work was well graced by the presence of Sir Henry Roscoe, Lord Lister, and other eminent men.

#### What Did Mr. Chamberlain Really Mean?

IN the course of a recent great public speech, Mr. Chamberlain made use of a simile not quite in tune with his usual brilliancy. Speaking of the internal dissensions of the Liberal party, he likened them to organisms of a low type called by naturalists fissiparous organisms, which fall to pieces at the slightest touch. Any schoolboy who has studied natural history for a term or two knows that fissiparous division is a peculiar method of reproduction and is independent of outside physical violence. If the Liberals are in an active state of fissiparous division they are on the high road to become a huge numerical army, for that particular method of reproduction proceeds at a phenomenal rate. Mr. Chamberlain certainly did not convey that impression. The risk of similes is proverbial, especially when taken from fields with the topography of which the author is not altogether familiar.

#### Suggested Alteration of Title, Royal Medical Benevolent College.

LORD ROSEBERY, the President of the Epsom College, objects very much to the full name and title of this institution. His idea is that to call Epsom College the Royal Medical Benevolent College is to use a superabundance of adjectives. Even the boys at Epsom College, according to Lord Rosebery, dislike the full name with its many epithets, and certainly the suggestion that the insti-

tution should be called Epsom College, with the words Royal Medical Foundation in brackets below, is worthy of all consideration. The Treasurer, Dr. C. Holman, who undoubtedly has considerable influence in the matter, will not consent to shortening the name because it may affect the amount of subscriptions. This, of course, is a perfectly reasonable opinion, and few men are in a better position to judge of the correctness of the conclusion than Dr. Holman.

#### Cough.

A SIMPLE faith in the efficacy of cough mixtures is apt to be rudely shaken by the study of the numerous reflexes through which the exciting impulse may travel, independently of pulmonary and bronchial irritation. We are told that there are fourteen recognisable varieties of useless cough, that is to say, cough which has not for object to rid the respiratory apparatus of irritating secretions. It is a matter of clinical experience that quite a number of coughs are caused by some abnormality in the nose, ear, and throat, while others are, with equal plausibility, ascribed to disordered states of the stomach or some other distant organ. This fact adds singularly to the difficulties with which the physician has to contend in his endeavour to ascertain the source of, and to relieve, the cough. One of the most fruitful sources of reflex cough is the presence in the nose or pharynx of varicose veins or some form of local hypertrophy, consequently the examination should commence in these regions. The root of the tongue is a common site of varicosities, but the epiglottis is often involved, and if success is to attend our efforts to relieve local treatment is indispensable. Apart from obvious structural changes, the existence of hyperæsthetic areas on the nasal mucous membrane and on that of the vault of the pharynx may and do determine a dry, irritating cough, exceedingly difficult to subdue, except by the discovery and treatment of such areas. The probability of a cough being of reflex origin may be inferred when it is spasmodic, practically constant, and accompanied by little or no expectoration, especially when signs of pulmonary disease are absent and when the symptoms persistently resist all medication for permanent relief. The presumption is strengthened if the general health is not thereby obviously affected, and the diagnosis will be absolutely confirmed when, upon removal of the assumed cause, it promptly disappears.

#### An Overlooked Factor in Ear Disease.

THE remedial treatment of ear disease culminating in deafness is, on the whole, so unsatisfactory that every suggestion as to causation is worthy of passing consideration. That the field of investigation is as yet far from closed is evident from the comparative inefficacy of the means employed for the relief of such conditions. In a recent number of the *Journal of the American Medical Association* Dr. Jackson calls attention to the influence of hypertrophic thickenings on both sides of the vomer near

the posterior free margin. The effect of these hypertrophies is to deflect the incoming blast of dust-laden, cold, dry air, and to cause it to impinge on the Eustachian eminences, thus setting up a chronic state of irritation of the mucous membrane in the vicinity of the tube mouths. This action, he points out, is independent of any harm such hypertrophies may do in increasing pre-existing stenosis. These growths are usually soft, though but slightly erectile, and, like the anterior spurs, which however are soft only at first, they are produced by the vascular stasis resulting from pressure against the membrane covering the vomer by the hypertrophied or swollen turbinals, usually the inferior. Normally the inspired air deposits suspended particles in three places before it reaches the larynx. First, on entering the nose the current passes upwards and strikes against the anterior inferior portion of the septum and the anterior end of the middle turbinal. Thence the current is deflected and strikes the posterior pharyngeal wall. In the normal nose the Eustachian eminence is well out of the way of the blast of air, but the presence of abnormal thickenings of the kind described directs it on to the Eustachian areas, and in this way may ultimately determine the form of deafness dependent upon obstruction of this channel of aerial communication with the middle ear.

#### Fads in Medicine.

A FAD in medicine may be defined to be a trivial fancy adopted and pursued for a time with irrational zeal, or a matter, whether important or unimportant, imperfectly understood and taken up and urged with more zeal than sense. Fads of this kind are certainly more common in medical matters than in any other department. Although the tenacity and frequency of such fads are usually in direct proportion to the ignorance of the faddist, we are fain to admit that a tendency to fads is occasionally met with even among the followers of *Æsculapius* themselves. Every new remedy, introduced with a flare of trumpets into therapeutics, becomes for a time the subject of the faddist, but this, perhaps, is more or less inevitable, because those who have hitherto failed to obtain the relief for which they crave from existing remedies are certain to give a trial to every new claimant to their confidence. The worst form of fad, however, is that which leads its victim voluntarily to restrict his diet, either in quantity or by the elimination of many useful articles of food. Another is that in which the faddist pins his faith to some nostrum of unknown composition, and administers it to all and sundry with touching indifference to their special symptoms. It is especially on the borderland of medicine that the fad flourishes most freely. Osteopathy, Christian Science, are modern examples of the "fad gone mad," but hypnotism and electricity for long years defrayed the craving of the ignorant for a universal panacea. Human nature forbids the hope that the fad will ever be exterminated, but it is all-important that medical men should jealously guard their independ-

ence of mind and steer clear of unjustifiable faith in any particular measure or group of measures for the cure of disease. To yield to such a tendency is to degrade the practice of medicine and to abandon all the advantages associated with the progress of science.

#### "Higher" Dental Degrees.

IF there be any one thing that has done more than another to bar the unity and the progress of the medical profession as a whole, that accursed thing is the multi-portal system of entrance into the inner precincts of qualification. That fact stands out as a kind of rock which the medical reformer selects as the base of his operations. For generations past those who have been crying in the wilderness for changes that are still to come have inscribed upon their banner the watchword of a one-portal system. It certainly savours of the backward path, therefore, when the dentists begin to create distinctions and variations of examination standard in their special qualifications. Something of the kind, however, appears to be in the mind of those responsible for the regulations of the University of Birmingham. They do not propose to grant any qualifying licence to practice dental surgery, a position that is understandable enough. What they have done is to invent a new degree in the shape of a Bachelorship of Dental Surgery, which is open to those who have obtained a registrable license elsewhere at least a year previously. The curriculum involves several extra subjects and extra courses, and the examination in the case of anatomy and physiology will be identical with those passed by ordinary medical students. Why a young and enterprising University should revert to the exploded multi portal system at this time of day is an inexplicable mystery.

#### Instrumental Imperfections.

IN no department of surgery, perhaps, is it more necessary for the operator to pass his instruments in review before using them than in laryngological and nasal work. Several instances are on record in which the nozzles of insufflators or sprays have become detached and have actually fallen into the larynx or even beyond, with, in some instances, very untoward and even fatal results. One such incident occurred in the practised hands of the late Sir Morell Mackenzie, and although his distinguished patient ultimately coughed up the foreign body it was not until after a period of intense anxiety to all concerned. More recently two cases have been reported in which the curette used for the removal of adenoids broke off at the junction of the sharpened spoon with the shaft. In one case the piece was removed without incident. In the other it was swallowed, and the piece was passed in the stools three days later. Similar accidents have occurred in the hands of dentists, and have given rise to actions for damages, happily unsuccessful, because it is hardly fair to hold the dentist responsible for defects which he could hardly be expected to be cog-

nisant. The moral is that care should be taken as a matter of routine to inspect an instrument before using it. The consequences of the entrance of a foreign body into the trachea are such as to make the boldest shudder, in view of the extreme difficulty of removing the intruder.

#### The Results of Four Years' Inoculation against the Plague.

IN a recent number of the *Indian Medical Gazette* Major Bannerman, I.M.S., gives the results of four years' experience of preventive inoculation in restricting the spread of plague. Up to the end of last year no less than 1,628,696 doses of anti-plague vaccine had been issued from the Plague Research Laboratory at Bombay, and in all cases in which accurate returns were obtainable, Major Bannerman is enabled to state that "without exception there has been a striking reduction in plague mortality, and a markedly favourable effect on the case incidence has been produced." The returns which he gives from the various plague centres appear to justify this encouraging statement, and they are well worthy of attention by those who are interested in forming a trustworthy opinion on the value of Professor Haffkine's method. We agree with our contemporary in the view that no one who studies this report can do other than believe in the efficacy of inoculation as a protective measure against plague. Major Bannermann concludes his report with the assurance, based on experience, that, to begin with, inoculation is harmless, that when given in the incubation stage it appears in most cases to abort the disease; further, that inoculation confers a high degree of immunity against an attack, and thus reduces the number of cases, and that when an inoculated person is attacked his chances of recovery are greatly enhanced.

#### Can Anæsthesia be Induced During Sleep?

IN the course of a recent trial it was stated by an expert medical witness that it was not possible to produce anæsthesia in the case of a sleeping individual, and it does not appear that this statement was challenged in cross-examination. It might easily have been pointed out to the Court that no less an authority than Dolbeau found that only three persons awakened out of a series of nine to whom he administered chloroform while sleeping. Dr. Leonard Guthrie is said to have frequently attempted to have chloroformed children in their sleep, but without success; but on the other hand, Dr. Dudley Buxton has no doubt that chloroform may in some cases be so administered, though he is less sure about ether. These views have an important medico-legal bearing, because anæsthetics are sometimes administered with a criminal purpose. It is difficult to understand how ether can be used for successfully placing a sleeping person under anæsthesia, but it is asserted by Dr. Turnbull that either chloroform or ether may be administered during sleep without awakening the subject of the experiment. Dr. P. G. Paugh has reported three cases,

all boys between the ages of four and nine, in which he succeeded in accomplishing such anæsthesia. Chloroform was used in each case, and no great difficulty seems to have been encountered, the probability being that the patients in these cases were exceptionally heavy sleepers, in which case it is quite conceivable that an expert anæsthetist would not experience any insurmountable difficulty.

#### Camphor in the Treatment of Varicose Ulcers.

CAMPHOR is a drug which for many years was held in great esteem, especially in extra-professional circles, indeed the late M. Raspail founded a school of therapeutics which still rejoices in great popularity in France, based on the use of camphor internally and externally as a curative agent. Its anti-spasmodic properties, though well authenticated, have of late fallen into disrepute, or at any rate into disuse, and externally it is only employed in this country in the form of a liniment of which it is but a subsidiary constituent. Two German physicians have recently called attention to the value of camphor dressings in promoting the cicatrization of varicose ulcers of the legs which are notoriously refractory to treatment. They make use of an ointment containing 2 per cent. of camphor with from fifteen to twenty parts of oxide of zinc, or, if this be found too irritating, they prescribe a mixture of two parts of camphor with forty parts of zinc oxide, and fifty parts of olive oil. An alternative application is a solution of the drug in spirit, but this must only be applied after the ulcerated surface has been thoroughly cleaned of scabs and crusts by poultices. It is asserted that under this treatment the most obstinate ulcer will cicatrize within three weeks, which is more than is claimed for the much lauded oxygen treatment, over which, moreover, it has the advantage of being more generally applicable at a vastly smaller cost.

#### The Toxic Effects of Cantharides.

IT might be said that it was unnecessary to draw attention to the toxic properties of cantharides when externally applied; but we think that the younger members of the profession hardly realise the fact that not alone in the extremes of life, but that in young vigorous adults also this toxic effect is produced. Even in the lower animals the tendency to produce nephritis is well known. We must, however, make an exception in favour of the common hedgehog, M. Khorvat (*Vratch*, 1897) having failed to produce toxic symptoms in the animal by a free use of the drug. The difficulty the prescriber is placed in is that there is no means of knowing what class of patient the drug disagrees with. It is a safe rule never to apply a cantharidine blister to an infant; but all ages are liable to the toxin, and Signor Muratori (*Gas. Osped.*) has just published a case of severe nephritis following on the application to the back of the thigh of a cantharidine blister in an adult eighteen years old and in robust health.

### Calcium Carbide in Inoperable Uterine Cancer.

THE employment of carbide of calcium as an application in cases of inoperable uterine carcinoma dates from 1896, and it seems to have come into favour in the United States, though its use is not unknown in France and Germany. In contact with the secretions the carbide liberates acetylene gas, which is stated to have a distinctly escharotic action on carcinomatous tissue, in addition to its antiseptic action, which inhibits the bacteria of putrefaction, and, *pro tanto*, reduces the fœtidity. It transforms the necrotic area into a clean, contracting, granulating wound, and the tendency to hæmorrhage is greatly diminished. Its use is said to be unattended by any painful or injurious collateral effect, and it greatly adds to the comfort of the patient, whose death may thereby be indefinitely postponed. We are unable to detect in the claims that have been advanced in favour of this treatment any element of therapeutical novelty. Its effects, such as they are, can be obtained by less offensive agents, and the suggestion that it may in some cases produce a complete cure must be dismissed as absurd.

### Probable Origin of the Heat Wave.

REPORTS of the meteorological offices in America have appeared regarding the amount and extent of the atmospheric heat there and its results, but they have not yet, it seems, vouchsafed even a plausible explanation of the origin and maintenance of the phenomena of the heat wave. There may, however, here be hazarded a suggestion to satisfy the curiosity of the general inquirer that this abnormal air heat is probably local and not cosmic, and that there need be no fear of its spreading outside the States. The heat is not reported extending over the sea or the coasts, or in the great lakes, so that it is probably purely terrestrial and dependent on the condition of the soil or country surface. In the populated States the progress of colonisation has brought the deforestation of the valleys and hills, for the purposes of cultivation, tillage, and pasturage, roads, railways, and towns, with log huts, and firewood, and this clearance has extended into the plains and prairies, which also contribute a quorum by their fires. It is probably bringing slowly on a condition of the earth's surface there as appears in an exaggerated form in the deserts of Sahara, Persia, Australia, Mongolia, &c., where no vegetation exists for sheltering the bare earth from the hot sun, or attracting moisture from the clouds. The consequence of this would be aridity of the air over the country, and no moisture to take up the sun's rays by clouds, and this state of matters in the climate tends to repeat itself, and to prolong itself, till some atmospheric storm cyclone sweeps down from the tropic, or blizzard comes from the polar regions to disturb the heat bank formed over the States.

DR. E. K. BROWN has been appointed Medical Officer of Health for the borough of Bermondsey.

### PERSONAL.

MR. HENRY GREENWAY HOWSE, [F.R.C.S.Eng., M.S. and M.B.Lond., Senior Surgeon, Guy's Hospital, has been elected President of the Royal College of Surgeons of England.

MR. THOMAS RICHARD JESSOP, F.R.C.S.Eng., J.P., Consulting Surgeon, Leeds General Infirmary, and Mr. F. Howard Marsh, F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital, have been elected Vice-Presidents of the Royal College of Surgeons of England for the ensuing collegiate year.

DR. ANDERSON, who for about ten years has been the Blackpool Medical Officer of Health, has been appointed to a similar position at Capetown. The salary is £1,500 a year.

MISS MALCOLM, sister of Sir James Malcolm, Bart., of Balbedie, has bequeathed a legacy of £4,000 to St. Andrews University for the purpose of establishing medical bursaries or scholarships.

DR. A. E. PORTER, Assistant Medical Officer of Health for the county of Essex, has been selected out of nineteen candidates for the post of Assistant Health Officer for Leeds, at a salary of £300 per annum.

WE regret to learn that Dr. Gilles de la Tourette, a distinguished pupil of the late Professor Charcot, has fallen a victim to one of those mental maladies, in the cure of which he displayed such scientific zeal.

WE regret to record the fact that the death of Dr. James A. Myrtle, the popular Mayor of Harrogate, has been quickly followed by the sudden death of the Mayor of Bolton, Dr. J. E. Scowcroft. Both were in the prime of life and were performing their official and professional duties when stricken.

THE important post of Medical Officer of the Port of London, rendered vacant by the promotion of Dr. Collingridge, has been bestowed on Dr. Herbert Williams, who has been in the service of the Corporation since 1892 as Medical Officer at the Port Hospital, Gravesend, and who therefore has an intimate knowledge of the work and requirements of the Port. The salary attached is £650 per annum.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

#### THE ATTITUDE OF PHARMACISTS TO PATENT MEDICINES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—We were much interested by some editorials and correspondence which appeared recently in your columns regarding the attitude of pharmacists to the sale of secret nostrums. We feel sure that any pharmacists who have had the matter brought under their notice must feel under an obligation to you for ventilating a subject of such importance to them; and we are glad to learn that several of the leading houses in Dublin are seriously considering the adoption of the label suggested by Mr. Bernard, with the object of disassociating in the minds of the purchasers of secret remedies the fact that the sale of them by a pharmacist implies any recommendation by him. Acting upon Mr. Bernard's idea we had a label printed about twelve months ago as

follows:—"The composition of the contents of this package being unknown to us, we in no way guarantee its effects." We have not used this label very extensively, as we feared we might lay ourselves open to a libel action, and we find that the *Chemist and Druggist*, in a leading article in its issue of June 22nd, inclines to this idea. If it could be shown that the suggested label might be used with impunity, then we have no doubt but that it would become adopted by pharmacists generally, who do not at all love the sale of patent medicines, but are forced by the present attitude of the public towards them to bestow upon them an amount of attention entirely out of proportion to the remuneration gained. The pharmacists of Dublin have their thoughts at present centred on the British Pharmaceutical Conference which meets here the end of this month, and so are not able to discuss at the present moment this important subject; but we trust that during the coming winter something practical may be done.

We are, Sir, yours truly,  
J. GRAHAM AND CO.

[Our correspondents' fear that the use of a label such as they have had printed may involve them in a libel action, are, in our opinion, groundless. We are not in a position to give a legal opinion on this matter, but it appears to us:—

1. That the label in question is merely a statement of fact.
2. That it is affixed with the object of protecting the vendor.
3. That no jury taking into consideration 1 and 2 would decide that it was libellous. It is a matter on which the Council of the Pharmaceutical Society might with great advantage obtain a legal opinion.—Ed ]

VIRCHOW'S EIGHTIETH BIRTHDAY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I learn from Professor Waldeyer that Virchow's eightieth birthday will be celebrated in Berlin on Saturday, October 12th, when he will personally receive delegates with congratulatory addresses from various scientific bodies, foreign as well as German.

A preliminary notice of the intended celebration was given by Sir William Turner at the meeting of the General Medical Council last November to the representatives of the universities and medical corporations on that body; and if such of them as desire to be represented on the occasion will kindly send to me as soon as convenient the names of the delegates appointed I will communicate them to Professor Waldeyer, who is the president of the Executive Committee. Further particulars as to arrangements will be furnished later. The insertion of this letter in your columns would oblige.

I am, Sir, yours truly,  
LISTER.

12, Park Crescent, Portland Place, W.,  
July 6th, 1901.

THE SCIENTIFIC EDUCATION OF MEDICAL STUDENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It appears to me that in endeavouring to establish a sort of protection in favour of the medical schools, so far as the scientific education of the student is concerned, the General Medical Council has committed a tactical error which may be fraught with grave consequences. Whatever may be the case with the foremost metropolitan medical schools, it is a matter of common knowledge that the equipment, both in apparatus and in the teaching staff, in the smaller schools leaves much to be desired; indeed, I question whether the majority of them could adequately prepare a student in all branches of science for the preliminary scientific examination of the London University, for example.

But, after all, this is not the crux of the question.

There is no obvious reason why any restriction should be placed on students in this matter. All that the Council is concerned to know is that they have attained a proper standard of knowledge in these subjects, and if examinations cannot be trusted to elicit this fact they must be regarded as useless. The Council loudly proclaims its desire to insist upon five years of medical study, but elementary science is not medical study any more than arithmetic or geography. By all means let us have five years of *bona fide* medical study, to date from the time when these preliminary studies have been completed. I say it with reluctance, but I am fain to admit that the Council's attitude in this matter savours of a desire to increase the revenue of the medical schools, which is not exactly the purpose for which the Council was created. The cost of medical education is already exorbitant enough judged by that of other countries where the teaching is not one whit inferior to that in our own country, without artificially inflating the total.

I am, Sir, yours truly,  
POST-GRADUATE.

THE SUNDAY TIMES AND "SIR JOSEPH LISTER."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Sunday Times* is a bitter opponent of vivisection. The opening of the new pathological department at the London Hospital gave it abundant opportunity for caustic comment. Unfortunately, the sub-editor has allowed the name of Lord Lister to appear more than once as "Sir J. Lister"! This seems not a little curious in an up-to-date censor of the morals of the medical profession.

I am, Sir, yours truly,  
SCRUTATOR.

CHLOROFORM DEATH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With regard to your remark as to the death of a child at Guy's Hospital, a week or two ago, that there was no evidence as to how the chloroform was administered, I may say that being present at the inquest I can supply the information. The chloroform was given by the "open" method. The operation was for emphysema of the lung, and death resulted from suppression of breathing in a puny child, the subject of chronic tuberculous disease. The case shows how difficult it is to expect exact evidence from newspaper reports.

I am, Sir, yours truly,  
PRACTITIONER.

Literature.

CABOT'S PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST. (a)

THIS book, we are told in the preface, is intended for students, and a very useful guide it will be. The descriptions are faithful and good, and the abundant illustrations aid much in making that which is described plain and clear. We cannot agree with the statement that "Nothing is less like a barrel than the 'barrel chest.'" As depicted in the figure, page 15, a good type is given of one form of asthmatic thorax, but this is quite unlike the true "barrel chest" of chronic large lunged emphysema, of which an excellent drawing will be found on page 16.

The instructions as to percussion, specially as to light percussion, are to be commended to the notice of all students.

The author is all in favour of binaural stethoscopes, provided they be not jointed, and numerous illustrations are given of ordinary binaurals and also of the recently invented Bowles stethoscope. This

(a) "Physical Diagnosis of Diseases of the Chest." By Richard C. Cabot, M.D., Physician to Out-patients, Massachusetts General Hospital; Assistant in Clinical Medicine, Harvard Medical School. With 142 illustrations. London: Baillière, Tindall, and Cox. 1901.

stethoscope in its ordinary and multiple forms is fully described. Its value in recognising superficial and fine râles we have proved. The old wooden instrument fails to obtain a notice in this very modern work, though Broadbent and other English observers believe that the slight jar communicated to the ear by the rigid instrument helps to distinguish the first from the second cardiac sound. The remarks on the relative intensity of the pulmonic second sound as compared with the aortic, based on the observations of Dr. Sarah A. Creighton, are interesting as showing the effect of age on this sign. In almost every individual over sixty years of age the aortic second sound is louder than the corresponding sound in the pulmonary area.

The diagrams which are shaded where the murmurs are best heard ought to be very helpful to the student.

At the end of the book some well executed radiographs and fluoroscopic pictures will be found. Those of phthisis in various stages at page 301 (after Walsham) show how far this art has hitherto progressed.

The instructions to guide the observer in cases of early phthisis are given with accuracy; so too are those regarding large lunged emphysema. Atrophic, small lunged emphysema, receives but scanty notice.

A useful addition to the next edition of this book would be a chapter on tubercle bacilli, though this is a matter which does not strictly fall under the head of physical diagnosis.

#### SCHAFER'S "TEXT-BOOK OF PHYSIOLOGY." (a)

THIS huge volume concludes the magnificent encyclopaedia of physiological knowledge which does honour alike to its editor and to the various members of the staff of co-workers. The preceding volume having been issued about three years previously, the only feeling of regret which we experienced on examining that now before us was that a portion or portions of its contents had not been doled out to us long ago. It would relieve the growing feeling of scientific hunger which the good things of its predecessor had made us feel, and from which we suffered in direct proportion to the unprecedented value of its contents. It would also have made the first stage of the mental digestion of the present more enjoyable. Magendie's now too frequently ignored stage of "*prehension*" loomed up before us in all the grandeur of its gloomy responsibility when we greedily laid hold of this voluminous octavo, and became for the first time conscious of its *weight*!

The subjects are numerous, and, as the following list will show, have been judiciously distributed. That of the Mechanism of the Circulation of the Blood has been dealt with by Leonard Hill; Contraction of Cardiac Muscles by W. H. Gaskell; Animal Mechanics by J. B. Haycraft; Muscular and Nervous Mechanisms of the Respiratory Organs, of the Digestive Tract, of the Urinary Tract, and of the Generative Apparatus, by E. H. Starling; Mechanical, Thermal, and Electrical Properties of Striped Muscles, by J. Burdon Sanderson; Nerve, and the Physiology of Electrical Organs, by Francis Gotch; The Nerve Cell, by E. A. Schäfer; The Sympathetic and other Related Systems of Nerves, by J. N. Langley; The Cerebral Cortex, by E. A. Schäfer; The Spinal Cord and the Parts of the Brain below the Cerebral Cortex, by C. S. Sherrington; Vision, by W. H. R. Rivers; The Ear and Vocal Sounds, by John Gray McKendrick and Albert A. Gray; The Sense of Taste and Smell, by J. B. Haycraft.

With such a list of subjects of surpassing importance, and such a staff of authorities to supply information, it may well be expected that the volume under notice should form a necessary part of the mental equipment of every living physiologist and practical physician. Even the most accomplished of the former cannot have already been a master of all the scientific facts and theories which are here to be found, and it is the imperative duty of the latter to the public, to endeavour to make himself master of them as rapidly as he can. There is no

longer any excuse as the material has been placed within easy reach, and this monumental work penetrates the onset of a new era in the history of of physiology in English-speaking countries. It need no longer be said, as it often has been in our hearing, that the first necessary step in becoming even a moderately-skilled physiologist is the acquisition of a sound knowledge of the German language. We can now boldly say that we have as good teachers and as sound theorists at home, and point to the text-book now completed under the editorship of Prof. Schäfer as incontrovertible proof of the truth of our assertion. We need not repeat the old formula of wishing this work all the success it deserves. We feel sure that it *must* have it. We look forward for an early issue of a second edition—and this, we hope, divided into a much greater number of parts.

### Obituary.

#### DEPUTY-INSPECTOR-GENERAL RICHARD DOMENICHETTI, M.D.

THE death is announced, at Woodhall Spa, on Friday last, of this gentleman, at the age of 78. He was the eldest son of the late W. L. Domenichetti, 95th Regiment and graduated at Edinburgh in medicine in 1845, serving afterwards in the 8th King's Regiment and 1st Gordon Highlanders (75th Foot). Dr. Domenichetti was present as senior medical officer in the actions preceding the capture of Cawnpore and the relief of Lucknow, and received the thanks of the President of the Council of India for his services before Lucknow in 1857, with the medal and clasp. Dr. Domenichetti, after retiring from the service, received the honorary title of Deputy-Inspector-General, Army Medical Department, subsequently acted for 25 years as medical officer of health at Louth, Lincolnshire. In 1895 he was appointed Honorary Physician to Queen Victoria, and in 1897 received the Queen's Jubilee Medal.

### Medical News.

#### Society for Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the directors of the Society was held on July 10th, the President, Mr. Christopher Heath, being in the chair. Seven new members were elected, and the deaths of four members were reported, and the election of a member declared void. Two fresh applications for grants were read from widows and grants at the rate of £50 a-year made. It was resolved that a sum of £1,284 be distributed among the fifty-two widows, fourteen orphans, and six recipients from the Copeland Fund. The expenses of the quarter amounted to £45 13s. 0d.

#### The Electrical Ozon and Light Treatment.

A MAGNIFICENT installation for the application of the combined electrical, ozone, and light treatment, introduced from America, was opened by a musical *soirée* at 14, Hanover Square, W., on Tuesday of last week, when Mr. Purcell Jones, Mr. Maurice Farkos, Mrs. Max Langemann, and last, but not least, Signor Ancona, delighted a select audience. The visitors, among whom were many well-known metropolitan medical men, were then shown the various appliances for the utilisation of actinic rays produced by a large number of incandescent lamps in a suitable *baignoir*, the atmosphere whereof is largely composed of nascent ozone generated by very powerful Tesla coils. High tension currents traverse the body without the production of any disagreeable sensations, and these currents are applied locally by means of specially constructed vacuum electrodes. Apart from a slight hitch due to the melting of the main fuse the demonstration was very successful and excited great interest. It is hoped that medical men will inspect the very complete and costly installation, and we are pleased to note that in order to secure as far as possible the scientific application of the method, patients will only be admitted

(a) "Text-Book of Physiology." Edited by E. A. Schafer, LL.D., F.R.S. Vol. II. Pp. 1,365. Edinburgh and London: Young J. Pentland. 1900.

to treatment on the recommendation of their medical men.

#### Death from Chloroform.

An inquest was held at Nottingham on the 5th inst., on the body of a little girl, *et.* 7, who had succumbed to chloroform administered for the purpose of removing enlarged tonsils. It was pointed out that ether would not have been suitable for so young a patient, and the usual verdict was returned.

#### Annual Temperance Breakfast of the British Medical Association.

We are asked to announce that the usual breakfast given by the National Temperance League in connection with the British Medical Association annual meeting, will be held on Thursday morning, August 1st, at eight o'clock, in the Parish Room, St. James's Square, Cheltenham. The secretary (Mr. Rae, 34, Paternoster Row, London,) will be glad to send cards of invitation to any of our readers desirous of attending.

#### Health of Belfast.

THE report of the Medical Officer of Health for the year 1900 has just been issued. In the course of it Dr. Whittaker states that although the population of the city has increased during the past year, yet the deaths were less numerous than in either of the two preceding years, numbering 7,642 from all causes, whilst the numbers in the years 1898 and 1899 were 7,768 and 7,933 respectively. The number of deaths from zymotic causes were 50 per cent. less than in the four preceding years, although this decrease does not apply to typhoid fever, the deaths from which still keep abnormally high. Of the number of deaths registered during 1900, 2,899 were attributed to chest affections, and 737 to zymotic diseases—making a total of 3,636, or nearly one half of those registered as having died from all causes. Dr. Whittaker complains that there is no city in the three kingdoms of any importance in which the hospital accommodation for those suffering from infectious diseases is so limited as Belfast. Practically there is but one hospital—the Union—available for the purpose. The total accommodation therein is 250 beds. There were treated in it during the past year 1,261 cases. Although the necessity for an infectious diseases hospital for the city has been long acknowledged, yet but little has been done towards the erection of one. Plans, however, have been prepared and adopted by the Public Health Committee, and he hopes that during the year active measures will be taken to see to the completion of the building.

#### Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, was held at 429, Strand, London W.C., on 28th ult. There were present Dr. de Havilland Hall, in the chair; Dr. J. B. Ball, Dr. Fredk. S. Palmer, Mr. J. Brindley James, Mr. F. S. Edwards, Dr. M. Greenwood, Dr. St. C. B. Shadwell, and Mr. Horatio P. Symonds (Oxford). The accounts presented showed that the business was satisfactorily progressing. For the time of the year, the sickness claim account was moderate, and a larger number of new members than usual indicates that the advantages of the Society are becoming more recognised by the profession. Few claims were being received for accidents, and a very moderate number of influenza cases had been recorded this year; while the list of members receiving permanent provision of the Society was growing very slowly, as the additions to it were about counterbalanced by losses through death. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

#### Royal Medical Benevolent College, Epsom.

ON July 9th the Earl of Rosebery, K.G., President of the College, presided at the twenty-eighth festival dinner in aid of its funds at the Hotel Cecil. After the loyal toasts had been honoured, Lord Rosebery proposed the toast of the evening, "Success to Epsom College." As President of the College he suggested that he would like to see the title changed and the institution called simply Epsom College, with the words "Royal

Medical Foundation" as a sub-title; he did not see why Epsom College should not rise to the level of Eton. Present statistics showed that there were fifty foundation scholars in Epsom College for whom exhibitions had to be found from some fund or other, and then there was a difference which had to be met from public funds for those who were sons of medical men and those who were not sons of medical men, besides a considerable number of pensioners. That represented a sum of some £8,000 a year. The fixed income of the establishment was not one-third of that, and considerable reinforcements were required from outside. We have elsewhere referred to the salient points of Lord Rosebery's brilliant speech, which he closed with a strong appeal to the very large company present with the assurance that everything they gave would be well and worthily expended, and that they would have done no better deed in their lives than by assisting to maintain that noble institution. Dr. Holman, the treasurer, followed with an eloquent and at the same time a very practical reply. Personally, he did not object to the change of name proposed by Lord Rosebery, and if those present and their friends would only make the position of the pensioners and foundation scholars secure the adjectives might go; but the difficulty which he had each year to meet expenditure convinced him that unless people had a *quid pro quo* they would not give the money, and the omission of the words "Medical Benevolent" might result in a considerable loss of subscriptions. That was painful for him to say, but it was true. If the Council were provided with £50,000 they would wipe the whole thing out as regards benevolence altogether; but he did not feel justified in doing so without that security. Epsom College was mainly built by John Propert and members of the medical profession, and Propert could scarcely do less than call a college "medical" which was built by the funds of medical men. With regard to the benevolent part, he had seen in his long life the enormous amount of misery among his professional brethren, by sickness, death, and other misfortunes necessarily connected with an extensive and at times dangerous calling, to relieve which in a very humble way Propert instituted the two classes of pensioners and foundation scholars. The needs of the school amounted to about £8,000 a year, though the numbers varied considerably. Since he (Dr. Holman) had been treasurer some £17,000 or £18,000 had been apportioned to foundation scholarships and pensionerships. To diminish in any way the amount of relief which had hitherto been afforded would result in incalculable misery. The toast of "The Chairman" was proposed by Dr. J. L. Propert, a son of the founder of Epsom College, in felicitous terms. Subscriptions to the amount of £4,127 were announced during the evening, including 100 guineas from the Chairman and a donation of 1,000 guineas from an anonymous friend who had been moved to generosity by Lord Rosebery's speech. Lord Rosebery having briefly replied, the proceedings terminated. Thanks to the dinner committee, the arrangements were of the most perfect kind, and a most pleasant evening was the result.

#### The Mortality of Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 144, Bombay 41, Madras 43, Paris 17, Brussels 13, Amsterdam 14, Copenhagen 14, Christiania 10, St. Petersburg 24, Moscow 46, Berlin 17, Hamburg 14, Breslau 23, Munich 21, Vienna 17, Prague 23, Buda-Pesth 16, Trieste 23, Rome 16, Venice 17, Cairo 34, Alexandria 32, New York (including Brooklyn) 17, Philadelphia 15.

#### Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.

A SPECIAL examination for the Diploma in Public Health was held in Edinburgh in June, and the following candidates having passed the First and Second Examinations, received the Diploma in Public Health:—Mrs. Euphemia Stoker, L.E.C.P. and S.E., Sheffield; Major Robert Caldwell, F.R.C.S., Eng., R.A.M.C.; George Melville, M.B., C.M., Penicuil, and James Sinclair Tait, F.R.C.S.E., St. John's, Newfoundland.

## Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at the office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

### PROPOSED EXAMINATION QUESTIONS FOR FOURTH YEAR STUDENTS.

An irrepressible correspondent has inflicted the following upon us:—

What is the most suitable treatment for chimney sweeps' cancer? How would you proceed to disgnose mitral regurgitation in the fetus third month of pregnancy?

When performing the operation of ovariectomy would you pocket the fœe or the pedicle first?

The extirpation of the uterus and the complete occlusion of the vagina has been recommended as the radical cure for "leucorrhœa." Can you suggest a milder form of treatment, and one equally successful?

Is the reduction of hernia always accompanied by a guttural sound? What is the largest dose of iron you would shrink from taking (ironically speaking)?

Stale bread has been highly spoken of as a cure of juvenile consumption. Explain the rationale and give the author's name.

Why is "opening medicine" prohibited in cases of swallowing penknife or scissors?

How would you proceed to treat a case of chronic vomiting in which the patient "threw up" his employment?

A. D.

MR. J. M. M.—We cannot trace the article to which you refer. Our French correspondent drew attention to the "injection of quinine in the treatment of cancer" in one of the March issues.

S. E. R. will find his communication has been utilised editorially in our present number.

### THE ANTI-MICROBIC MANIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In these days of sterilised milk, &c., &c., when war is waged against the microbe, I was much interested in observing four begrimed dustmen, fresh from their work, sitting on their baskets by the roadside eating their breakfasts. Their hands were simply black, and yet the gusto with which they enjoyed their thick slices of bread and butter (or more probably "margarine") eaten from their dirty hands direct, would, I fancy, be an eye-opener for the bacteriologist, who would probably (like the barbarians, Acts, chap. xviii., verse 6) look "when they should have swollen or fallen down dead suddenly." "Surely extremes meet, and it would be most instructive to discover the average mortality among dustmen, who must, in London alone, number a small army. Go to the dustman, thou bacteriologist, consider his ways, and be wise.

I am, Sir, yours truly,

ALEXANDER DUKE.

Cheltenham.

RUS IN URBE.—We agree with you that the Finsen light treatment has not yet been placed upon a sufficiently sound scientific basis to warrant the claims made on its behalf. The physicians whose names are connected with the method would do better to discourage newspaper notoriety, at any rate in the tentative stage of the treatment.

W. E. G.—We fear that the drug in question has not fulfilled its earlier claims to confidence. At the best it could only act as a palliative to some of the minor symptoms of the disease in question. As a matter of fact, the condition may be relieved if not cured by the prolonged administration of thyroid gland.

### LONDON SALT EATERS.

THE *Revue Internationale de Therapie Physique* is responsible for the following, which will certainly be news for Londoners:—"Since the English have learnt from the American newspapers that salt is a panacea—a kind of veritable elixir of life—its consumption has considerably increased in all the London restaurants. An English journalist has 'interviewed' the principal restaurant keepers in the City and the West-End, who everywhere declare that the salt-cellar is emptied in the twinkling of an eye. They have now to fill salt-cellar many times a day which formerly still contained salt at the end of a week. Indeed, a restaurant keeper in Leicester Square declared that, on Saturday last, he completely ran out of salt in the evening, and in consequence was put to a great deal of

trouble. *Habitues* of large restaurants continually ask for very salt dishes to be served several times a week, such as 'pickled pork' and 'blusters.' 'C'est une rage, une furie.' In London everything at the present moment is salt. Salt has become the king of comestibles. And still numerous Londoners complain bitterly that during the Exhibition of 1900 the Parisian restaurant keepers salted them too heavily." *Cum grano salis.*

## Appointments.

BAMFORD, T., M.R.C.S. Eng., L.R.C.P. Lond., Medical Officer of Health of the Uttoxeter (Staffordshire) Urban Sanitary District.

BARLOW, T. W. N., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Camb., Medical Officer of Health for the Borough of Bootle, and Visiting Medical Officer of the Linacre Hospital.

BROWN, B. C. M.B., B.C. Camb., Medical Officer of Health of Diss (Norfolk) Urban Sanitary District.

COOPER, LUDFORD, L.R.C.P. Lond., M.R.C.S. Eng., Assistant Ophthalmic Surgeon to St. Bartholomew's Hospital, Rochester.

DUNN, F. H., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health of Stevenage (Hertfordshire) Urban Sanitary District.

EDWARDS, R. J. LL., M.B., C.M. Glasg., Medical Officer for No. 1 District and for the Workhouse of Swansea Union.

FAOAN, F. J., F.R.C.S., Lecturer on Elementary Physics at the Catholic University, Medical School, Dublin.

GRIFFIN, W. WATSON, M.B., F.R.C.S. Eng., Ophthalmic Surgeon to the Sussex County Hospital, Brighton.

HUGHES, JAMES BRIDLEY, M.R.C.S. Eng., L.S.A., Consulting Medical Officer of the Macclesfield General Infirmary.

HUGHES, JOHN B., M.B., B.C. Cantab., M.R.C.S., member of the Honorary Medical Staff of the Macclesfield General Infirmary.

MEIKLE, R. H., M.B., C.M. Glasg., Medical Officer of Health of the Darlington Rural District.

PROBYN-WILLIAMS, E. J., M.D. Durh., Lecturer and Instructor in Anesthetics at the London Hospital.

WADE, CHARLES, L.R.C.P. Lond., M.B.C.S. Eng., Medical Officer for the Boacastle District of the Camelford Union.

## Vacancies.

Bishop Auckland.—Medical Officer of Health for the Rural District. Salary £350 per annum. Whole time to be devoted to the office. Applications to the Clerk of the Council, Bishop Auckland.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, washing, and residence; also Junior, £75 per annum, with board, residence, and washing.

Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board (excluding stimulants) and apartments.

University of Sydney, New South Wales.—Professor of Pathology. Salary £900 per annum. Pension £400 per annum after twenty years' service. £100 allowed for passage. Further particulars of the Agent-General for New South Wales, 9, Victoria Street, London, S.W.

## Births.

WHITELOCKE.—On July 8th and 9th (midnight) at Banbury Road, Oxford, the wife of Richard Henry Anglin Whitelocke, M.B., M.Ch., F.R.C.S. Eng., of twin daughters.

## Marriages.

CHARLES—HODGSON.—On July 8th, at the Parish Church, Hands-worth, Staffordshire, John Roger Charles, M.D., to Alice Mary Gertrude, daughter of the Venble. Robert Hodgson, rector of the parish and Archdeacon of Stafford.

CROFTS—HENDERSON.—On July 10th, at St. Peter's Church, Leicester, George Harry Crofts, M.R.C.S., L.R.C.P., son of John E. Crofts, of Leicester, to Margaret Mary, eldest daughter of Duncan Henderson, of Leicester.

HANSON—WALLIS.—On July 10th, at St. Saviour's Church, Eastbourne, Basil Francis Hanson, youngest son of H. J. Hanson, Esq., of Lilecotes, Marlow, Bucks, to Maud Bath, youngest daughter of the late G. A. Wallis, Esq., M.I.C.E., J.P., of Eastbourne.

HUNNARD—POOLE.—On July 9th, at Llanbeblig Church, Carnarvon, by the Rev. J. W. Wyan Jones, Arthur Hunnard, M.B., B.S. Lond., to A. E. Cicely Poole.

KNOX-ROCHE.—On July 9th at the Parish Church, Weston-super-Mare, by the Rev. E. Morris, Robert George Knox, M.R.C.S., L.R.C.P., to Annette, daughter of the late Mr. Francis Roche.

STOKES—GREY.—On July 9th, at the Church of St. Michael and All Angels, Bedford Park, London, John Wilfred Stokes, M.R.C.S., L.R.C.P. Eng., to Doris Louisa, daughter of Mr. and Mrs. Gray.

## Deaths.

BAGOT.—On July 7th, at Leinster Square, Dublin, Edward Bagot, F.R.C.S.I., late of Enniskillen.

DE'ATH.—On July 7th, at Buckingham, George Hanby De'ath, L.R.C.P. Lond., M.R.C.S. Eng., aged 39 years.

HALLIDAY.—On July 8th, at Nottingham Street, Marylebone, Middleton Wood Halliday, L.D.S., R.C.S. Eng., aged 60 years.

MOSES.—On June 3rd, at Amoy, China, of typhoid fever, John Moses, M.R.C.S., L.R.C.P. Eng., aged 31 years.

NICOLA.—On July 8th, at Chautmont-Vexin, France, Thos. Low Nichols, M.D., aged 85 years.

WARNEFORD.—On July 10th, of pneumonia, at Paignton, Devon, Chas. F. Warneford, M.D., late Surgeon H.M. Indian Army aged 79.

### THE COMPLICATIONS AND DEGENERATIONS OF FIBROID TUMOURS OF THE UTERUS AS BEARING UPON THE TREATMENT OF THESE GROWTHS. (a)

By CHARLES P. NOBLE, M.D.,

Surgeon-in-Chief, Kensington Hospital for Women, Philadelphia.

THE traditional teaching concerning fibromyomata of the uterus is, that these tumours are of frequent occurrence; that only exceptionally do they produce grave symptoms; that after the menopause they tend to undergo a spontaneous cure; and that only in the rarest instances do they cause death. This teaching, while traditional, has never been universally accepted. It has been combated from time to time by those having to deal with grave conditions arising from the presence of fibroid tumours. As early as 1853 the classical essay of Washington L. Atlee on "The Surgical Treatment of Certain Fibrous Tumours of the Uterus heretofore considered beyond the Resources of Art" appeared. (b) This essay largely consists of a description of the serious conditions resulting from fibroid tumours, together with an earnest plea for their radical removal. Until recently hæmorrhage has been considered the chief, if not the only danger arising from them. It is now appreciated that patients suffering from fibroid tumours are subjected to many other risks that arise from the degenerations and complications of these growths. Necrosis, myxomatous and cystic degeneration of the tumour, calcareous infiltration, associated malignant disease of the body of the uterus or of the cervix, and complicating diseases of the uterine appendages, such as ovarian tumours, pyosalpinx, salpingitis, &c, not to mention the more remote effects upon the alimentary tract, the cardio-vascular, urinary, and nervous systems, may cause death or continued invalidism of such patients, independent of the natural history of the tumour itself.

In estimating the risks of patients suffering from fibroid tumours the profession has been too prone to be guided by the teachings of the past, rather than by the results of the more careful observations of the present. The chief purpose of this paper is to present in detail the nature and complications of fibroid tumours as they are met with in actual practice. It is well known that fibroid tumours of the uterus are frequently complicated by other conditions, but accurate tables of considerable numbers of cases with their complications are conspicuous by their absence. As a contribution to the study of fibroid tumours I wish to report 218 cases, in which various operations have been performed. This report includes all cases of operation for fibroid tumours in my practice. An analysis of this

group of cases, showing the degenerations in the tumours and the various complications encountered, should give a more satisfactory picture of the condition of patients suffering from fibromyomata of the uterus than any merely theoretical consideration of the subject.

It will at once be apparent, from the accompanying analysis that fibroid tumours do not occur in actual practice as an isolated, uncomplicated, morbid condition. On the contrary, patients suffering from these tumours, as we meet them in the consulting-room and hospital, are found very frequently to have in addition serious complicating diseases, not only of the uterus and of its appendages, but also various morbid conditions in the body at large.

In the 218 patients operated upon for fibromyoma uteri to May 24th, 1901, the following complications were encountered:—

Appendicitis ... ..	4
Bilateral hydrosalpinx ... ..	8
Unilateral hydrosalpinx ... ..	5
Hæmato-salpinx ... ..	1
Calcareous infiltration ... ..	5
Cystic degeneration of ovaries ... ..	2
Ovarian cyst with twisted pedicle ... ..	1
Ovarian cyst, bilateral ... ..	2
Ovarian cyst, unilateral ... ..	19
Ovarian cyst, suppurating ... ..	1
Bilateral dermoid cyst; umbilical hernia ... ..	1
Dermoid cyst, suppurating, sinus through abdominal wall ... ..	1
Dermoid cyst with twisted pedicle ... ..	1
Intraligamentous development of fibroid ... ..	10
Retroversion of uterus ... ..	3
Procidentia of uterus ... ..	3
Parovarian cyst ... ..	2
Ectopic pregnancy ... ..	3
Papillary carcinoma of both ovaries ... ..	1
Abscess of ovary ... ..	1
Pyosalpinx, bilateral ... ..	5
Pyosalpinx, unilateral ... ..	3
Salpingitis, bilateral ... ..	2
Salpingitis, unilateral ... ..	5
Myxomatous degeneration of tumour ... ..	5
Cystic degeneration of tumour ... ..	5
Necrosis of tumour ... ..	12
Adeno-carcinoma of body of the uterus ... ..	3
Epithelioma of cervix uteri ... ..	4
Sarcoma ... ..	2
Syncytioma ... ..	1

In estimating the risks encountered by patients suffering from fibroid tumour we shall consider first those growing out of the complications themselves, which we shall classify in three groups. *First*, those which would lead to a fatal result; *second*, those which would threaten the life of the patient; and, *third*, those which would involve more or less invalidism.

1. Of complications which would lead to the death of the patient are the following:—

Ovarian cyst with twisted pedicle... ..	1
Ovarian cyst, bilateral ... ..	2
Ovarian cyst, unilateral ... ..	19

Carried forward ... .. 22

(a) Paper read before the British Gynecological Society, July 11th, 1901.

(b) "Trans." Amer. Med. Assoc., 1853, vol. vi., p. 547.

Brought forward ... ..	22
Ovarian cyst, suppurating ... ..	1
Bilateral dermoid cyst; umbilical hernia ... ..	1
Dermoid cyst suppurating, sinus through abdominal wall ... ..	1
Dermoid cyst with twisted pedicle ... ..	1
Ectopic pregnancy ... ..	3
Papillary carcinoma of both ovaries ... ..	1
Abscess of ovary ... ..	1
Pyosalpinx, bilateral ... ..	5
Pyosalpinx, unilateral ... ..	3
Cystic degeneration of tumour ... ..	5
Necrosis of tumour ... ..	12
Adeno-carcinoma of body of the uterus ... ..	3
Epithelioma of cervix uteri ... ..	4
Sarcoma ... ..	2
Syncoityoma ... ..	1
	68

To these must be added three cases of cancer of the cervix complicating fibroids, in which hysterectomy was not performed, reported in 1897. (a)

Also one case of epithelioma of the cervix complicating a fibroid tumour of the uterus, seen in consultation with Dr. W. Wayne Babcock in 1899, in which the patient's general condition forbade operation. Also a fifth case from my hospital service, reported by Dr. Babcock. (b)

This is Case 2 of Dr. Babcock's report, in which a fibroid tumour of the uterus was complicated by epithelioma of the cervix, making altogether twelve cases of cancer complicating fibroid tumour which have been encountered. Of these fatal degenerations and complications of uterine fibroids, making a total of seventy-one, thirty-two are of the uterus or tumour, and thirty-nine are of the appendages.

2. Of complications threatening the life of the patient are the following:—

Appendicitis ... ..	4
Bilateral hydrosalpinx ... ..	8
Unilateral hydrosalpinx ... ..	5
Hæmatosalpinx ... ..	1
Parovarian cyst ... ..	3
Myxomatous degeneration of the tumour ... ..	2
	23

3. Of conditions leading to more or less permanent invalidism of the patient are the following:—

Calcareous infiltration ... ..	5
Cystic degeneration of ovaries ... ..	2
Intraligamentous development of fibroid ... ..	10
Retroversion of uterus ... ..	3
Procidencia of uterus ... ..	3
Salpingitis, bilateral ... ..	2
Salpingitis, unilateral ... ..	5
	30

It is probably a moderate estimate that seventy-eight of these patients would have died if the complications of the fibroid tumour had they not been operated upon.

It is difficult to estimate the number of deaths which would have resulted from the symptoms produced by the tumours themselves—deaths due to hæmorrhage; to chronic anæmia, leading to degeneration of the heart and kidneys; to pressure of the tumour upon the ureters and bowels; to malnutrition induced by the hæmorrhages and by the increase of intra-abdominal pressure interfering with the functions of the alimentary canal; to the lowered vitality of the patients, increasing their liability to contract intercurrent diseases; to septicæmia from necrosis of the tumours; and to thrombosis and embolism through associated phlebitis. To these must be added the risks of pregnancy and parturition when complicated by fibroid tumour. It can hardly be considered as other than moderate if we estimate that fifteen of these patients would have died eventually as a result of the presence of the tumours, independent of the above complications. This would

make a total of ninety-three deaths in the 218 cases as a result of the tumours themselves or their complications, a mortality of 42 per cent.

In estimating the number of deaths which would occur from the various complications encountered there may be a difference of opinion as to the probable history of the special complications. It should be pointed out, however, that this would merely take away a small number from the list of deaths to add it to the list of invalids.]

It is impossible to know whether my own experience with the complications of fibroids has been an average one, or whether the cases of fibroid tumour coming under my care have been more or less complicated than usual. I am not familiar with similar tables of complications of fibroid tumour based upon a definite number of cases which would afford a basis of comparison. Martin (a) reports the following complications and degenerations:—

Complications of Fibroid Tumours met with in 205 Cases.

Fatty degeneration of tumour ... ..	7
Calcification of tumour ... ..	3
Suppuration of tumour ... ..	10
Edema of tumour ... ..	11
Cystic degeneration of tumour ... ..	1
Teleangiectasis of tumour ... ..	3
Sarcoma of tumour ... ..	6
Carcinoma of cervix uteri ... ..	2
Carcinoma of corpus uteri ... ..	7
	50

It will be noted that he makes no reference to the condition of the appendages, and that thus his table can be compared only in part with my own.

It may be urged with reason that some of the cases included in this table might have been otherwise classified. The cases of cancer and sarcoma of the uterus complicating fibroids and the cases of large ovarian tumours might perfectly well have had a different classification, and in this way the list of complications having a fatal termination would have been decreased. But even allowing for such a difference in classification there can be no doubt that at least a third of the patients would have died as a result of the tumour or their complications.

Some of the more striking complications which have been encountered will next be considered, in order to illustrate more clearly the nature of fibromyomata of the uterus.

One undoubted case of sarcoma of the uterus had the following history: Mrs. G., æt. 51, childless, had been in failing health for more than a year. She had had a fibroid tumour of the uterus for years, which had recently taken on renewed growth.

The tumour was the size of a foetal head. Abdominal section, Feb. 2nd, 1893, revealed a very soft tumour of the uterus, with secondary growths in the left broad ligament. Upon subsequent microscopical examination, the tumour was pronounced a sarcoma. The uterus and its appendages were removed by hysterectomy. The patient died after a few months from the rapid development of the secondary sarcoma in the broad ligament and abdomen. (b)

A case of syncytioma had the following history:—Mrs. K., æt. 31, has had two children and one miscarriage, which occurred between the two labours at term. The

(a) Martin, A., "Pathology and Therapeutics of the Diseases of Women," Boston, 1890, p. 268-272.

(b) I have seen a second case of undoubted sarcoma of the uterus. This was a case of recurrent spindle-celled sarcoma of the cervix. The first tumour was removed at the Women's Hospital of Philadelphia, and the second at the Kensington Hospital for Women. Each time when the patient came under observation the tumour was necrotic, making hysterectomy inadvisable and each time the patient refused radical operation after recovering from removal of the sloughing tumour. This sarcoma was pediculated, and was not associated with a fibroid tumour.

A somewhat doubtful case is that of Mrs. W., operated upon September 19th, 1895. A fibroid tumour undergoing regenerative changes was removed, and a clinical diagnosis of sarcomatous degeneration was made. The pathologist reported that this was probable, but that the tumour was too necrotic for a positive diagnosis. The patient died subsequently of disease of the liver, believed to have been a secondary development of the tumour.

(c) Noble, Charles P., "The Development and Present Status of Hysterectomy for Fibromyomata," "Trans." Amer. Gynec. Soc., 1897, p. 38; *British Gynec. Jour.*, 1897, vol. xiii., p. 48.  
(d) *Amer. Gyn. and Obs. Journ.*, 1898, vol. xiii., p. 402.

youngest child was thirty months old when she consulted me, June 20, 1893. Menstruation was normal until nine months before she came under observation, since which time she has been bleeding almost constantly. She suffered from pronounced anæmia, corresponding with the history of the hæmorrhage. On examination, the uterus was found enlarged by a tumour in the fundus. A diagnosis of fibroid tumour with probable cancer of the endometrium was made. A combined vaginal and abdominal hysterectomy was performed on June 29th, 1893. A fairly normal convalescence followed. She died early in the December following, about five months after the operation. Death was due to secondary involvement of the left lung, and there were numerous small tumours under the skin scattered over the body. When the specimen was examined after operation, a clinical diagnosis of fibroid tumour of the uterus undergoing sarcomatous change was made. The final report of the pathologist is that the case was one of syncytioma. (a)

The two cases following were operated upon during pregnancy:—

1. Mrs. A., æt. 38, nullipara, was pregnant two months. Shortly after becoming pregnant she discovered an abdominal tumour, which on examination proved to be freely movable and pedunculated, very soft to the touch, and was believed to be an ovarian cyst. Abdominal section was performed, December 3rd, 1894. On delivering the tumour it was found to be a soft fibroid with a slender pedicle, which was injured in the delivery of the tumour. This made the removal of the fibroid preferable to its return, in spite of the complication of pregnancy. The pedicle was ligated and divided. The patient made a good recovery from the operation, but unfortunately aborted. Subsequently she gave birth to a living child.

2. Mr. P., æt. 37, mother of four children, suffered markedly from pressure symptoms, due to a large rapidly-growing fibromyoma. Pregnancy was suspected. This was believed to add to the indication for hysterectomy because of the size of the tumour. Hysterectomy was performed June 20th, 1898. Recovery was uninterrupted. Examination of the specimen showed the existence of a twin pregnancy of six weeks.

Of the twelve cases of necrosis of the tumour six occurred in submucous fibroids or fibroid polypi, the necrosis being due to interference with the circulation by the efforts of the uterus to throw off the tumour. In these cases the tumours were removed by operation *per vaginam*. Two died: one from embolism resulting from a septic inflammation antedating operation and persisting after it; the other from advanced endocarditis.

Of the six cases of necrosis of the tumour operated upon by abdominal section all were in bad condition from septic absorption. All would promptly have died from septicæmia without operation. Three succumbed to septicæmia. One died of embolism of the brain. Of the twelve cases of necrosis six died and six recovered, showing the extreme gravity of this condition.

A striking illustration of the fact that the menopause need not bring relief to a patient suffering from a fibroid tumour is the case of Mrs. C., æt. 67, the mother of one child, æt. 40, who consulted me for the relief of intolerable bladder symptoms. She suffered constantly from tenesmus of the bladder, which had resisted long-continued treatment in the hands of others. She had suffered from hæmorrhage of the uterus from the age of thirty-five until the menopause was established at fifty-two. Examination showed a multinodular fibroid tumour, the pelvic portion of which had become calcareous. The subsequent investigation of the case proved that, by pressure on the right ureter, the calcareous portion of the fibroid had caused degeneration of the right kidney. Operation was performed, March 6th, 1900, at the urgent request of the patient, in spite of a bad prognosis, in the hope that the removal of the tumour might afford an opportunity to relieve the bladder symptoms. She died four days later of suppression of urine.

In this connection and as bearing upon the behaviour

of fibroid tumours after the menopause, reference will be made to the case of a physician's wife, seen in consultation some years ago, who had suffered from the age of thirty-five to fifty-three from uterine hæmorrhages before the menopause was established. Subsequently her health improved, but she was never a vigorous woman. When about seventy years of age, after a drive on a rough country road, the tumour became necrotic. An abscess developed, which ruptured into the bowel. A drainage operation was performed, but the patient died septic.

The disappearance of fibroid tumours after the menopause and after labour is a part of the classical teaching concerning the life history of these growths. My own experience adds little in support of this teaching. No instance of a fibroid tumour having disappeared after the menopause has come under my notice. In one case, seen fifteen years ago, a fibroid tumour was said to have greatly lessened in size after labour, as compared with its size before pregnancy. No other similar case has come under my observation since. That one having large opportunities for observation could have had this experience indicates that the disappearance of fibroid tumours as a result of the menopause or as a result of pregnancy is not to be expected. This occurrence is merely one of the curiosities in the history of these growths.

The ages of the patients operated upon, grouped in decennial periods, were as follows:—

Under 20	...	...	...	...	...	1
Between 20 and 30	...	...	...	...	...	6
Between 30 and 40	...	...	...	...	...	77
Between 40 and 50	...	...	...	...	...	76
Between 50 and 60	...	...	...	...	...	20
Between 60 and 70	...	...	...	...	...	7

The remaining thirty-one cases were operated upon *per vaginam*. In these cases the histories are not complete. One of them was between fifty and sixty, and a number between forty and fifty.

From the standpoint of the youth of the patient the following are of decided interest: One, æt. 17; one, 22; one, 24; and one, 26.

The history of the youngest patient is as follows: Miss T., æt. 17, began to menstruate at 13. Menstruation was regular for five months. It then ceased for two years, with the exception of two periods. She then menstruated every two or three weeks, and from July, 1890, until December, 1890, when she consulted me, she had been bleeding constantly. The patient complained of extreme debility from loss of blood. Upon examination a fibroid tumour was found choking the pelvis and, extending half-way to the umbilicus. Operation, March 23rd, 1892.

From the standpoint of the age of the patient it is of great interest that twenty-one patients, including one operated on *per vaginam*, were between 50 and 60 years of age, and seven patients between 60 and 70 years of age. The oldest patient was aged 67. It will be observed that over 12 per cent. of the patients were above 50 years of age when their symptoms caused them to seek relief in operation, at which time, according to the classical teaching concerning the life history of fibroid tumours, most of the patients should have regained their health as the result of the influence of the menopause. The teaching that the menopause ensures the symptomatic cure of the patient does not receive much support from these figures.

It is not feasible to give the exact age at which menstruation ceased in patients operated upon after the forty-fifth year. A large percentage of them menstruated until they were past fifty, and one as late as the fifty-fifth year. No fact in connection with the history of fibroid tumours is more evident than that the menopause is delayed for from three to ten years.

The relation of fibromyomata to sterility is indicated by the fact that of the 218 patients operated upon, only ninety-one had been pregnant. Of the 127 who had not been pregnant, a certain percentage were unmarried. This experience is in accord with the accepted belief that fibromyomata are a cause of sterility.

(a) McFarland, Joseph, "A Case of Deciduoma Malignum," "Proc.," Pathological Soc. of Phila., 1900, vol. iv., p. 86.

In the list of complications no mention was made of the question of adhesions. In numerous cases adhesions were a marked feature—intestinal, appendicular and vesical. This was more especially true when the tumour was complicated by salpingitis in its various forms. Adhesions are often the cause of pain, constipation, and disorders of digestion, and a source of added risk at the operation. Extensive adhesions add definitely to the risks of operation, by increasing the mechanical difficulties encountered.

The relation of fibroid tumours to phlebitis and embolism both before and after operation is well recognised. In 1889, before hysterectomy for fibroids was well established, I saw a well-marked case of phlebitis consequent upon inflammatory changes in a fibroid tumour. In 1900 a very striking case of phlebitis and embolism, with death, came under my observation. Mrs. D., *æt.* 46, multipara, when standing upon a ladder working with the arms extended, was suddenly seized with violent pain in the abdomen, followed by collapse and grave peritonitis. After several weeks the peritonitis improved, but was followed by phlebitis involving the veins on the left side of the neck and left axilla. She apparently made a good recovery from this condition, but some weeks later died of embolism of the brain. The peritonitis was due to torsion of a pedunculated fibroid, resulting in necrosis of the tumour.

Another death from embolism was that of a patient operated upon when septic, as a result of sloughing of a fibroid polypus. She died from embolism twelve days after operation, her temperature never having become normal.

Phlebitis following operations for fibroids is quite common. The exact pathology of phlebitis is imperfectly understood. It is the tendency of surgeons to attribute all accidents following operation to infection, but in many cases of phlebitis following hysterectomy and myomectomy, the *role* of infection is difficult to prove or to believe. The most prominent characteristic of a series of cases of post-operative phlebitis is that the patients almost, if not without exception, are anæmic and prostrated.

The most characteristic symptom of patients suffering from fibromyomata of the uterus is anæmia. It is not feasible to give the exact percentage of patients suffering from marked anæmia in this group of cases, as many of them were operated upon before the present methods for the study of the blood were in use. A large percentage were anæmic, and some of them in the highest degree. The following case illustrates the degree to which anæmia may develop as a result of hæmorrhage:—

Miss E., *æt.* 45, was admitted to the hospital, January 16th, 1901. She was markedly anæmic, the skin having a waxy appearance, and her hands, ears, &c., being characteristically translucent. She had been bleeding almost constantly for months. Examination showed a number of fibroid nodules, and also a small tumour of the right ovary. It was evident that the condition of the patient forbade a radical operation. The uterus was curetted on the 19th, with the hope of controlling the uterine bleeding, so that with proper feeding and treatment her blood state could be improved to the point rendering a radical operation feasible. On the 23rd examination of the blood, gave the following result: Erythrocytes, 2,325,000; hæmaglobin, 10 per cent.; poikilocytosis marked; leucocytosis marked, of the usual type. On February 6th, the following: Erythrocytes, 2,760,000; hæmaglobin, 35 per cent. On March 4th, the following: Erythrocytes, 3,640,000; hæmaglobin, 45 per cent. Miss E. was discharged March 6, 1901, with the advice that she should return for a radical operation so soon as her blood condition had somewhat improved. She was again admitted April 2nd, and on the 4th hysterectomy by supravaginal amputation was performed, removing the fibroid tumours and the ovarian cyst. The blood examination on the 3rd showed: Erythrocytes, 3,770,000; hæmaglobin, 55 per cent. The examinations of January 23rd and April 3rd were made with Gower's hæmaglobinometer, that of March 4th with Fleischel's instrument, and that of the 6th with the instruments of both Gower and Fleischel. The pathologist's notes concerning the examination of January 23rd state that the

estimation of the hæmaglobin was very difficult because of the excessive hæmaglobinemia. The blood was a slightly turbid straw-coloured liquid.

After the curettage Miss E. was extremely ill. Her pulse was very feeble and prostration was extreme. After the hysterectomy she made a good recovery.

It seems hardly credible that a patient could live with such a high grade of anæmia—only 10 per cent. of hæmaglobin. Had the blood-count been made before the curettage was done it is doubtful whether it would have been undertaken, as the danger of administering ether under such conditions is well recognised.

In others of the graver cases of anæmia the result was not so fortunate. The risks of shock, of œdema of the lungs and of septic infection, after operation, are all increased in anæmic patients.

The attitude of those advocating what they call the conservative plan of treatment of fibroid tumours, but which would more properly be called the expectant mode of treatment, with reference to hæmorrhage from fibroids, is difficult to appreciate. They agree that when a patient has become profoundly anæmic from hæmorrhages, operation is indicated, but oppose operation before that state has been reached. It would seem much more logical to operate early, thus preventing the development of a profound degree of anæmia, saving the patient months or years of invalidism, lessening the immediate risks of the operation itself, and very greatly shortening the period of convalescence after operation. When anæmia has become profound and of long duration, at times it is incurable, and usually appropriate treatment must be continued many months to bring about a cure. The secondary effects of chronic anæmia are also difficult to cure, and should therefore, be avoided. This is especially true of the effect upon the nervous system.

The progressive anæmia often engendered by fibromyomata of the uterus has a distinct bearing upon the operative mortality. In certain cases in which a palliative line of treatment has been followed, it may become imperative to operate, despite the transgression of Mikulicz's rule: Never to operate in any case when the hæmaglobin is below 30 per cent.

A certain proportion of deaths also results from thrombi formed in the vessels of the tumour, which, becoming detached, produce emboli and infection in the lungs and other viscera. Besides these alterations in the blood, degenerative changes in the form of fatty degeneration, brown atrophy, hyaline degeneration, and atheroma, have been found in the walls of the heart and blood vessels in numerous cases. Over fifteen years ago, Hofmeier (*a*) collected seven cases of uterine fibromyoma, in one of which sudden death resulted from pulmonary embolism, in two from a high grade fatty degeneration, and in four from brown atrophy of the heart muscle.

In a number of my own fatal cases the immediate cause of death was the rapid onset of pulmonary œdema. Whether in those cases the pulmonary œdema was an extension of an embolic process in the lungs, or from myocardial degeneration, I am unable to say, as it was difficult to secure thorough post-mortem examinations.

Carcinoma and fibroma being such common diseases, it would be expected that they should frequently co-exist in the uterus. In proportion to its relative frequency, the adeno-carcinoma of the uterine body is more often in this association than is the more common squamous epithelioma of the cervix. That the irritative action of a fibroma should predispose to the development of the adeno-carcinoma would seem slightly less plausible than that laceration of the cervix should predispose to that of epithelioma of the cervix. Clinical experience and embryological studies both refute the idea, however, that the benign tumour may undergo carcinomatous transformation. Indeed, even the penetration of the capsule of the fibroid by an adjacent carcinoma is extremely rare. In two of my cases the carcinoma had reached the capsule, but there was no tendency to

(a) Hofmeier, M., Zur Lehre vom Shock (Ueber Erkrankung der Circulations-Organen bei Unterleibsgeschwulsten), *Zeits. f. Gebur. u. Gyn.*, 1885, Band xi., p. 366.

penetrate the substance of the fibromyoma. Von Becklinghausen observed several cases of adeno-myomata in which the glandular tissue present seemed to have acquired malignant properties.

Sarcomatous degeneration of fibroids would seem to be possible, yet the close histological similarity between fibro- and spindle-celled sarcoma and fibromyoma renders it difficult for the pathologist to determine whether a given growth has been malignant from its inception or has been the result of a sarcomatous degeneration in a fibroid. It is generally accepted, however, that the benign tumour may undergo this transformation.

Of the cases of epithelioma of the cervix complicating fibroid tumour of the uterus, one is of special interest, as it occurred in a virgin. Miss H., *et. 54*, was admitted to the hospital, March 26th, 1901. She had been in failing health for a year, the prominent symptoms being increased menstrual flow, dyspeptic symptoms, increasing debility, inability to retain urine, and neurasthenia. On examination there was found an epithelioma of the cervix complicating multiple fibroid tumours of the uterus. The epithelioma was first curetted and burned away. Total hysterectomy was performed on the 28th. An enlarged gland was found over the iliac vessels. This was removed, and under microscopical examination proved to be a secondary squamous cell epithelioma. A good recovery followed, with the disappearance of all symptoms.

According to the classical teaching concerning the history of fibroid tumours, a fatal termination is very rare. At the present time it is not difficult to understand why this is true, because when the condition of patients suffering from fibroid tumours becomes grave, whether from hæmorrhage, repeated attacks of peritonitis, disturbances of the digestive organs, of the vascular system, or the urinary organs, they are submitted to operation. Patients operated upon when in bad condition swell the mortality of operations, and also greatly increase the list of those making poor recoveries after operation. Doubtless in the future the number of cases dying directly as a result of fibroid tumours or their complications will be less than in the past, because in a larger percentage an early operation will be performed. Nevertheless, numerous cases of death from fibroid tumours can be found in the literature. Bishop (a) reports 37 fatal cases which he has collected.

If the cases of fibroid tumour of the uterus which have come under my observation can be taken as representing these growths as a class, it is a fair conclusion that death will result in more than one-third of the cases. In more than one-fourth of the cases the result will be chronic invalidism. This percentage of invalids would be increased by the percentage of cases ultimately ending in death, so that from one-half to two-thirds of the patients having fibroid tumours, which have come under my observation, have been confirmed invalids. Of the remainder, about one-third, but few have not been incommoed to a considerable degree as a result of the presence of the tumours. The percentage of cases in which tumours have been found more or less accidentally is quite small. This estimate of the gravity of fibroid tumours is radically opposed to the classical teaching upon this point.

It is gratifying to contrast the results which can be secured through the resources of modern gynecology with those which follow an expectant plan of treatment. The mortality of hysterectomy and myomectomy is variously estimated at from 2 to 10 per cent. In a series of 345 cases published by myself in 1897 (b), the mortality of hysterectomy by supravaginal amputation in the hands of five American gynecologists was 4.9 per cent.; in a series of 100 total hysterectomies, the mortality was 10 per cent. In a collection by Olshausen (c) of 806 cases of supravaginal amputation the mortality was 5.6 per cent., contrasted with a mortality

of 9.6 per cent in a collection of 520 cases of total extirpation. According to Bishop (*l. c.*) Mr. Christopher Martin reports thirty-five cases of total extirpation, with a mortality of 2.8 per cent.; Doyen, sixty cases, with a mortality of 2.6 per cent.; A. Martin, eighty-one cases, with a mortality of 7.4 per cent. The advocates of vaginal hysterectomy for fibroid tumours report equally as good, if not better results. The results of myomectomy indicate that enucleation is a more dangerous operation than hysterectomy, although, in the hands of trained men, the results are excellent. Kelly (a) reports ninety-seven myomectomies, with four deaths. This is to be contrasted with 307 hysteromyomectomies, with fifteen deaths, or a mortality of 4.8 per cent. reported in 1900. MacMonagle (b) reports sixty-five cases of myomectomy, with no death.

From these reports the estimate that the mortality of hysterectomy and myomectomy varies from 2 to 10 per cent., depending upon the gravity of the cases, upon the operator, and upon the environment in which the operations are done, is quite justified.

We are now able to contrast the mortality of fibroid tumours, including that of their degenerations and complications, with the mortality of operation—upwards of 33.3 per cent, with less than 10 per cent.; also the morbidity incident to the history of fibroid tumours as compared with that which follows operation, in which the comparison is very much in favour of operation. From all the facts presented, the conclusion is inevitable that the proper treatment of fibroid tumours of the uterus is their early removal. Early operation not only greatly lessens the mortality, but what is of more importance, it saves the long period of invalidism, which is otherwise unavoidable.

Believing that the best treatment of fibroid tumours in general is their early removal, the question remains whether there are no exceptions to this rule. The best answer to this is that each case must be decided upon its merits. It is my individual experience that small multinodular subperitoneal fibroids in women of forty years of age or more are the least apt to grow and to cause serious symptoms. Conversely, submucous and intramural fibroids in younger women are the most apt to develop and to cause serious trouble. It has been my experience to meet with but few fibroids which were not producing symptoms, and it is, therefore, my belief that the percentage of cases is small in which operation is not more advisable than expectancy.

## Paris Clinical Lectures.

### MEDICAL TREATMENT

OF

## CANCER OF THE STOMACH.

BY CHARLES ROBIN, M.D.,

Professor of Clinical Medicine, University of Paris.

[REPORTED BY OUR PARIS CORRESPONDENT.]

It appears strange to make this question the subject of a lecture when it is known that gastric carcinoma is an incurable lesion. But I want to show you how you can and ought to improve the condition of these unfortunate patients. When I was a student I was painfully struck by the lamentable state of *abandon* in which these cancerous patients were left. I have seen the best professors manifest complete indifference towards them. Milk diet, injections of morphine when pain was intolerable, iron where there was hæmatemesis, and that was the end of the therapeutic treatment. It was naturally insufficient; by reason of the apathy of the physician, surgeons claimed the treatment of cancer, so much so that at present 75 per cent. of the patients who enter the hospital submit to a curative or palliative operation—pylorectomy and gastrectomy on

one hand, gastro-enterostomy on the other. I think it necessary, consequently, to react and to warn you against this tendency, which appears to me to be excessive. For this reason I wish to speak to you to-day on the medical treatment of cancer; we will study later on under what conditions an operation would be justified.

The treatment of gastric cancer aims at a double end: attenuate the sufferings of the patient, nourish them and prolong their existence as long as possible.

The hope of an ultimate cure must be encouraged, and the treatment should be to that end, as there exist other curable affections of the stomach that might be confounded with cancer.

Some years ago I observed in this sense a typical case: a man who presented the classical signs of epithelioma of the stomach—dark vomiting, tumour, emaciation, cachectic condition, &c. In conformity to the rule which I have just indicated, I reserved my diagnosis, and treated the case on its merits; two months later the patient left the hospital cured. It was a false cancer. It is evident that the milk diet alone would have given the worst result. The medical treatment of cancer is consequently more complicated than would first appear. We are going to see what it is.

First of all, you must not fall into the error that we have at our disposition a specific medication for cancer, and yet some distinguished *confreres* have thought at one time to have discovered a curative therapeutic agent. It is thus that Cabazès thirty years ago proposed the employment of *condurango* for the cure of cancer. Rives related that out of fifty-one patients that agent gave him four cures. These results required confirmation. But *condurango* is none the less a useful remedy as a stimulant to the appetite and the digestive functions. It is given under the form of decoction, extract or tincture. The decoction is made with two drachms and a half of the bark in eight ounces of water boiled down to five ounces and fifteen drops of hydrochloric acid added after the secretion is filtered. The patient takes three or four table-spoonful daily. The extract is given at the dose of two to ten grains daily, and the dose of the tincture is from ten to fifty drops daily.

A second therapeutic agent enjoys great favour since the interesting communication made by my friend and colleague, M. Brissaud; I allude to chlorate of soda.

For a long time chlorate of potash was employed in epitheliomata of the tongue and the skin. M. Brissaud did not adopt this agent because it is a poison of the blood transforming the oxy-hæmoglobine into methemoglobine. The author in his communication cited five patients absorbing from two to four drachms daily of chlorate of soda, a dose impossible in the case of chlorate of potash. Under the influence of this treatment the patients were much improved, the cachexia disappeared, and in one case in six weeks the mæna and hæmatemesis had ceased.

Our own experience, and that of several authors, brought me to conclude that if chlorate or soda had not a specific action on gastric epithelioma, it at least acts as a tonic, increases the strength of the patients, and stimulates the appetite. I must not forget, however, to mention one counter indication to the employment of chlorate of soda, and that is the presence of albumen in the urine.

A host of other remedies have been proposed as specifics; I will only mention the principal substances.

Bichromate of potash was recommended by Vulpian at the dose of one grain daily; it irritates the stomach; it should not be employed.

Tincture of *thuya occidentalis*, which had its day,

was recommended at the dose of four drops at each meal, and increased gradually to 100 drops daily. It increases the weight of the patient, and might be ordered.

The extract of chelidoine was proposed by Gré-sensko to cure cancer in general, either as a local application on external cancers such as that of the breast, or used internally against the cancerous diathesis. I have not obtained any good results from it, and cannot advise you to try it. I pass rapidly over other substances such as calago, employed by the doctors of Paraguay, sulphate of aniline, pyocetanine, chloride of gold and sodium, bromide of gold associated with arseniate of soda; all these products have a more or less hurtful effect on the gastric membrane. There remains the important questions of serum and beer yeast, but they belong as yet to the experimental period, and nothing positive can be said of them, although it is possible that useful results may be reached.

To sum up, all the drugs proposed as specifics of cancer should be regarded simply as stimulants of the appetite. The curative treatment does not exist practically by medical means. We will see in another lecture what must be thought of surgical interference.

## THE DETECTION OF LOCULATED FLUIDS IN THE ABDOMEN.

By GEO. M. FOY, M.D., F.R.C.S.,

Surgeon to the Whitworth Hospital, Drumcondra.

SIR THOMAS WATSON, in his classic lectures, writes; "The parietes of the fore part of the belly being soft and flexible you might naturally suppose that the physical morbid conditions they cover would submit themselves to an easy diagnosis. But the truth is . . . the diseases of the abdomen are more hard to discriminate than the diseases of the thorax." Bright taught his class to note "the form and appearance presented to the eye, the form still further discovered to touch, the resistance ascertained by pressure, the sounds elicited by percussion, and, in a few instances, the sounds perceptible to the ear, either alone or by aid of the stethoscope."

M. Louis Rostan (*Traité Élémentaire de Diag.*) illustrates the necessity for the exercise of caution in such cases by the following: An old woman, a patient in his hospital, complained of a severe pain in the abdomen, towards the left iliac region. Her face was flushed, her skin hot, her pulse strong and frequent, her tongue dry, and she was very thirsty. The abdominal pain was aggravated by pressure, and by the movements of the patient. Upon these data M. Rostan diagnosed abdominal inflammation, and he prescribed accordingly. One of his pupils, however, lingered behind, and having removed the patient's chemise saw that the trouble proceeded from an attack of shingles. To-day the physician, when the ordinary methods of diagnosis fail him, calls the surgeon to his assistance, and a laparotomy for purposes of diagnosis is a justifiable and recognised proceeding, but such a step cannot be rightly taken until the less serious methods have been tried, and as a valuable addition to these we wish to bring forward the bimanual method of percussion for the detection of cystic or loculated fluids in the abdomen, as recommended by Dr. John Clark, of Philadelphia.

On bimanual examination of a pelvic mass of questionable consistence, the intestines intervening between the anterior abdominal wall and the tumour may dissipate the percussion impulse of the abdominal hand, and although fluid may be present, a wave of sufficient intensity to be felt by the

vaginal touch is not induced. To overcome this difficulty Dr Clark confines the tumour as closely as possible between the two examining hands, while the percussion is made by an assistant. "With light, quick taps, even small collections of fluid may be detected by the quick, responsive, pulsatile wave passing from the abdominal to the pelvic hand."

In tumours other than pelvic the method has been modified. By pressing one hand deeply in over the hypochondrium, while with the other deep counter pressure is made just below the fixed ribs, the author was able to detect an appendical abscess situated beneath the cæcum and the lower lobe of a downward displaced liver.

Such cases and such tactile methods of diagnosis require from the physician the *tactus eruditus* which comes of long practice and careful observation; but which is almost a lost art since scientific instruments have become so generally adopted. To those who possess the gift the bimanual method of percussion cannot fail to be helpful, and it is worthy of a trial from all.

## CARDIAC DRUGS AND THE VASOMOTOR TREATMENT.

By PROF. GOTTLIEB,  
Of Heidelberg.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

SEEING that circulatory disturbances have for result to determine an unequal distribution of blood in the organism, the object of cardiac and vasomotor treatment must be to restore the equilibrium thus destroyed.

Paralysis of the blood vessels, due to the insufficient central innervation of the vasomotor centres, causes the blood to flow into the abdominal vessels, while the peripheral vessels and those of the skin and brain are depleted; the pulse is feeble and the heart only receives an inadequate supply of blood during diastole. This variety of circulatory inadequacy occurs in cases of intoxication resulting from the use of narcotics and during attacks of infectious disease. In such cases the exhibition of cardiac drugs would generally be without effect, since it is not the strength of the heart that is lacking, but that the quantity of blood which it receives is insufficient. But the blood withdrawn from the action of the heart and accumulated in the dilated vessels of the abdomen, can be brought back into the general circulation by the use of drugs acting upon the vasomotor system, through which they give rise to contraction of the vessels in the splanchnic area. To obtain this result, strychnine, camphor, and caffeine are prescribed. Much the same result may be obtained by irritating the skin, or by making cold applications.

Cardiac drugs are used for the purpose of restoring the energy of the heart. They increase the volume of systole, and in this manner tend to remedy the defective distribution of the blood in the organism, which is the usual consequence of most complaints of the heart, accompanied by a diminution in the energy of this organ, an accumulation of blood in the venous system and anæmia of the arteries being the inevitable result of incomplete systole and of insufficient ventricular diastolic aspiration.

Digitalis acts chiefly by strengthening the energy of the heart; its vasomotor effect is of secondary importance. From experiments made on the heart of a frog, it was long since observed that the cardiac systole increases, and that the energy of the ventricular contraction is strengthened under the influence of digitalis. Recently we have succeeded in making the same experiment on warm-blooded animals in

whom the heart was protected from the variable resistance of the general circulation. We are, therefore, no longer compelled to base our conclusions on experiments made upon frogs. By isolating the cardio-pulmonary circulation, following the example of François-Franck and of E. Hering and Bock, we are enabled to study the action of digitalis on the heart, independently of its effect on the vessels; we can also make use of a separated heart, in which the functions are maintained by an artificial circulation through the coronary vessels. I have been able to afford direct proof by this latter method that an increase in the volume of the systole takes place, and by the aid of a special arrangement I satisfied myself that after a dose of digitoxin the energy of the ventricle is trebled or quadrupled.

The increase in the volume of the systole is caused more particularly by a more complete contraction of the cardiac muscle; the ventricle emptying itself with greater facility. This action is the more important in connection with an ailing heart since a failing ventricle becomes less and less capable of getting rid of its contents. Moreover, the slight diminution in the frequency of the pulse, due to the stimulation of the pneumogastric, which occurs in addition to the more strictly cardiac effect under the influence of digitalis, has a beneficial influence on the cardiac function. The diastolic aspiration of the blood of the veins into the cardiac cavity is also favourably influenced by this slowing of the pulse. Consequently the efficacy of digitalis becomes very evident, in proportion as this slowing effect is manifested. The maximum effect of this treatment corresponds to complete expansion of the ventricles during diastole, plus a maximum contraction during systole. The heart in this way pumps a greater quantity of the blood which is contained in the over-filled veins, and propels it into the bloodless arteries.

All drugs acting in a manner analogous to digitalis have, in addition to the action on the heart, a vaso-constricting effect, as I was able to demonstrate anew in my recent experiments. But this vasomotor action is accessory, from a therapeutical point of view; the important factor in combatting venous stasis is an improvement in the cardiac function. The vascular contraction may be of some utility in the sense that the blood is thereby driven out of the congested portal system into other parts of the vascular system, for, in the first instance, it is principally on the portal vein that the vascular action of digitalis is produced; but, if this contraction exceeds certain limits, its beneficial effect is transformed into one very inimical to the organism, since, in consequence of the rise of arterial resistance the work of the heart is needlessly increased.

Camphor does not only act on the heart indirectly through the vasomotors, it also directly increases the irritability of the cardiac muscle. Its action on the normal heart is little marked; on the other hand I was able to convince myself in the case of the rabbit, that under certain pathological conditions, when the heart ceases to beat, it is possible by the application of camphor to combat this momentaneous stoppage and to save the rabbit's life.

Caffeine has a direct effect on the heart, but one quite different from that of digitalis nor can it be considered as a substitute for the latter. As a matter of fact it does not increase the functional energy of the healthy heart in cases where the blood tension is normal, but it strengthens the action of the cardiac muscle in the presence of a pathologically high arterial resistance; it may also be useful in cardiac complaints accompanied by a high aortic tension.

Alcohol has not a direct influence over the heart; it acts indirectly on this organ by diminishing the

peripheral resistance, when in consequence of an exaggerated aortic tension, the left ventricle can no longer completely empty itself. In this case it causes the vessels to dilate, and the resistance to diminish, and as a result whereof the heart carries on its work under more favourable conditions, and is enabled to furnish a greater amount of work.

The various cardiac drugs, it will be seen, act on the circulation in quite a different manner to those which act in the vasomotor system. In spite of the difficulties that present themselves in the study of so complicated a mechanism we may hope that by associating clinical observation with experimental pharmacology we may succeed, little by little, in gaining a deeper insight into the nature of the circulatory troubles which present themselves to our notice, and to choose with more discernment the treatments capable of combating these troubles and of restoring the equilibrium.

### Transactions of Societies.

#### BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

GENERAL MEETING HELD JULY 12TH, 1901.

Mr. MAYO COLLIER, F.R.C.S., President, in the Chair.

Mr. MAYO COLLIER showed a case of Double Optic Neuritis with Paralysis of both External Recti following Right Tympanic Disease. The interesting point was the cause of the neuritis. Dr. HAWTHORNE suggested cavernous sinus thrombosis; Dr. DUNDAS GRANT the possibility of tubercle. Dr. WOODS also spoke, and the PRESIDENT, in his reply, objected on anatomical grounds to implication of the cavernous sinus.

Mr. MAYO COLLIER also related a case of Deafness due to Chronic Sclerosis of the Middle Ear, which had been greatly improved after relief of nasal obstruction and showed a case of Epithelioma of the Maxillary Antrum nine months after operation, in which there had been, so far, no return.

Dr. BARCLAY BARON showed a case of Complete Aphonia with Close Approximation of the Cords. It had resisted all treatment, and was brought forward for diagnosis and suggestions for treatment. There was general agreement that the case was functional. Chloroform narcosis, hypnotism, and cauterly to the enlarged veins at the base of the tongue being variously proposed.

Mr. LENNOX BROWNE showed a specimen of a Fibromyxomatous Polypus, removed from behind the palate, and found to have proceeded from the maxillary antrum through the opening in the inferior meatus, made during the course of operation performed some months previously for relief of maxillary empyema.

Mr. LENNOX BROWNE exhibited a case of Pretuberculous Condition of the Larynx in a patient who had been treated by him twenty years previously for Traumatic Perichondritis due to the impaction of a chicken-bone in the larynx. The patient had since developed symptoms which pointed to tubercle, but both pulmonary and laryngeal evidences had been—to say the least—inconclusive. The main feature was recurrent aphonia, but with phonetic cough.

Mr. LENNOX BROWNE also showed a patient with Sarcoma of the Pharynx, who had been exhibited twice previously, first in March before removal, secondly in May after removal, and now again, to demonstrate, first that a certain amount of infiltration suggestive of a possible recurrence had entirely subsided, and secondly in regard to the epiglottis which formerly compressed by the growth had now entirely recovered its form and position.

Mr. LENNOX BROWNE showed a patient, æt. 66, with an enormous tonsil and glandular infiltration which had existed for three months, but up to

now, though causing comparatively little difficulty in swallowing, had been the occasion of severe pain. The microscopical examination revealed that the growth was a sarcoma, and it was suggested that, although quite inoperable, the case was one suitable for treatment by Coley's fluid, of which the exhibitor had had more than one favourable experience.

THE PRESIDENT, commenting on the interest of the case, expressed the opinion that the majority of malignant tumours of the tonsil are sarcomata.

Dr. McCOLL showed a patient suffering from Laryngeal Tuberculosis in an advanced stage, which had been treated by insufflations of resorcin and orthoform. Both deglutition and voice had been greatly improved, and the laryngoscope showed several cicatrices of healing. The general treatment had been that of "open air" and the patient had gained a stone in weight. The President, Mr. Lennox Browne, and Dr. Dundas Grant spoke in congratulatory terms on the result.

Dr. LODGE showed a patient with Lupus of the Nose cured by Excision according to the method of Anderson, with an artificial nose of aluminium made by the patient himself, who, a coachbuilder by trade, had achieved a success far exceeding that of one of ordinary manufacture which was exhibited for comparison.

Dr. DUNDAS GRANT showed (1) a case of Post-Diphtherial Paralysis; (2) Ulceration of the Tongue, probably malignant; (3) Thrombosis of the Jugular Vein.

Dr. WOODS (Dublin) opened a special discussion on  
TUMOURS OF THE PHARYNX FROM THEIR CLINICAL ASPECT.

He related several cases in his own practice both in the naso-pharynx and in the lower pharynx and his methods of operating. The chief interest turned on the advisability of operation.

Mr. LENNOX BROWNE spoke in favour of removal at the earliest possible moment after diagnosis and related several cases, and the PRESIDENT discussed the question from the point of view of surgical anatomy, giving several fatal instances which, from the experience of others, might have been successful had they been attacked with courage in their early history.

Dr. DUNDAS GRANT confessed himself at a loss to account for the undoubted hesitancy of even bold surgeons to interfere with these cases, considering the great advances that had been made in radical operations generally.

Dr. LODGE related a case, and showed photographs of a successful operation for removal of a sarcoma of the naso-pharynx and of involved cervical glands.

Dr. VINEACE drew attention to the success of the case of Mr. Lennox Browne, which, when first exhibited, was almost unanimously pronounced by the Fellows present to be inoperable.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 20th, 1901.

#### PATHOGENETIC STUDIES ON PHTHISIS, CANCER, AND SOME OTHER DISEASES.

THIS is the title of an interesting work by Professor Riffel Carlsruhe, in which he endeavours to show the origin of various diseases. The onset of various epidemics observed in four places possessing different kinds of geographical position, drinking water, subsoil, &c., has confirmed an idea already in his mind that the prime causes of diseases are to be sought in the individual himself, and in the peculiar character of his organs and tissues, which become changed from one moment to another, and not alone by the chemical and bacteriological examination of external things, nor by experiments on animals or infection of wounds. The author gives tables of family trees of about fifty

different families, and draws from this material his conclusion that tuberculosis is a distinct disease from phthisis, which is a necrotic process of the lungs dependent on congenital disposition or tendency. The prophylaxis of phthisis lies, therefore, in the avoidance of constitutional weakness. As medicinal means of improving the constitution are not always at hand, residence in mountain curative resorts is necessary, and the furtherance of these institutions is one of the most important hygienic objects.

By far the greater part of the cases of cancer observed by the author occurred in families in which phthisis also had occurred. The presence of the tubercle bacillus in broken down cancer masses is for him a proof of their saprophytic nature.

Regarding puerperal fever the author comes to the conclusion that women who belong to phthisical families are susceptible to septic diseases. With any suspicion of phthisis about them pregnant women in lying-in hospitals should be isolated.

He prophesies that the results of bacteriological achievements in regard to phthisis will eventually prove to be as small as that obtained from the Hamburg cholera epidemic in respect of that disease. In spite of a good deal that must now be considered heterodox in Professor Riffel's teaching, the factors of the individual himself, his organs, and his tissues has of late years been somewhat overlooked, and all disease has too generally been put down to "outside things."

At the Society fur Innere Medizin Hr. Litten related a case of

#### EMBOLISM OF THE PULMONARY ARTERY.

A woman of 70 was brought into hospital a few days ago with symptoms of myocarditis, extensive dyspnoea, irregular pulse, and albuminuria. Death took place suddenly through increased dyspnoea. Section showed the following conditions:—In the lungs firm large nodules, of which four or five appeared as prominences on the surface. They were hæmorrhagic in parts, as shown by cutting into them. The arteries leading to the nodules were blocked even up to the finest branches. On the hilus of the lungs was a large fleshy mass that came from the pulmonary artery of the left lung, which was completely blocked by an embolism the thickness of the thumb, so that not a single drop of blood could pass through it. Here was the cause of the sudden death. When the question came up: whence does this embolic material arise, there were two possible sources, either clotting in the veins or thrombi in the heart. In this case the latter were present; the left ventricle, which was exceedingly dilated, was filled with adherent thrombi; the left auricle with hæmorrhagic infarcts and thrombi in the right heart, especially in the auricle. The emboli had at first passed through the arteries of the lungs and set up the infarcts, and later blocking of the arteries themselves took place.

He remembered a case seen when he was assistant in Frerich's Klinik. A man, æt. 29, was taken in with severe dyspnoea, systolic and diastolic murmurs in the region of the pulmonary artery, and soon died. Section showed the following:—The trunk of the pulmonary artery and the two branches given off were filled with numberless echinococcus cysts, which filled up the lumen of vessels up to those of the third order. The systolic and diastolic murmurs were caused by the

emboli, which prevented complete closure of the valves. There was a question how long the man might have lived with this blocking of his arteries. A little blood might possibly have passed, and the section showed evidences of this in small blood clots at the peripheral ends of the embolus. Whence the echinococcus cysts originated was not ascertained.

The *Munch Med. Wochensch.*, 19/1901, contains the relation of a case of

#### GUNSHOT WOUND OF THE BLADDER

by Dr. Bayerl. A little boy, æt. 8, was accidentally shot by his brother by a small pistol. Examination revealed a small roundish opening just above the os pubis, the borders being bruised and blackened. The opening led to a small canal passing to the right, which could be followed a distance of 5 ctm. The bullet could not be found. From the opening trickled a small quantity of watery fluid (urine), slightly mixed with blood. The boy complained of strong desire to micturate. The next day matters had improved so much that clear urine was passed spontaneously from the urethra, but the next day they became worse again. There was great restlessness and excitement, violent pain in the scrotum with swelling, swelling at the fundus of the bladder, vesicular swelling at the root of the penis, and fever. No urine came through the wound. There was, therefore, infiltration of urine. A number of incisions were now made in the scrotum, penis, &c., and a good deal of urine escaped through the wounds. The pain ceased, however, and the swelling and fever subsided. Three days later the bullet was found in the dressings. Recovery with healing of the wounds now speedily followed, without any necessity for further surgical procedures.

The *Deuts. Med. Zeit.*, July 8th, reports a case of supposed

#### SYPHILITIC PARALYSIS AFTER CHLOROFORM NARCOSIS.

A patient, æt. 34, was operated on for hernia. The stage of excitement was so extreme that the man's arms had to be tied together. Afterwards the patient noticed that the left arm was quite powerless, and that the right arm could only be moved with difficulty. Twenty-three days after the operation the reporter of the case diagnosed bilateral paralysis of the brachial plexus. It was ascertained anamnæstically that the man was an alcoholic, and that five weeks before he had contracted a syphilitic infection. On treatment by inunction improvement took place, and in a few weeks complete recovery. The reporter attributes the paralysis to the syphilis, but paralysis under similar conditions is not unknown where syphilis is out of the question.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 20th, 1901.

#### LICHEN AND LUPUS.

SIEGFRIED JANOVSKY at the Prague meeting showed two cases of lichen and several of lupus.

(a) *Ruber planus* in the case of a female, æt. 57, scattered over the body and extremities as brown, flat, waxy lesions, with glancing, horny, shield-like appearance. Arsenic was administered with tar and hydrotherapy to relieve the itching. The disease improved slowly, leaving a brown sepia colour.

(b) *Ruber verrucosa* in a youth, æt. 19, localised on the lower extremities. The efflorescence appeared to be due to an excessive proliferation of the papilla. The feeble constitution and imperfect assimilation of food was in favour of Robinson's theory of the cause of the disease, viz., a great enfeebling of the individual and diminished resistance of the body.

Lupus erythematosus in a typical facial form.—Patient a female, married, æt. 35. Various remedies were applied till erysipelas commenced on the healthy side and extended to the affected side. On recovering from the erysipelas the lupus disappeared also.

The next case was that of a male, æt. 49, which was peculiar from the hyperkeratosis developed on the affected side.

Janovsky related a number of similar cases to the first which were cured with Koch's tuberculin contrary to the opinions of French authors. In seems that the toxin from the tuberculous bacilli has some beneficial effect on lupus erythematosus by awakening some centre not reached by external applications.

The best therapeutic for lupus vulgaris was scarification after Brock's method. He cannot speak favourably of Holländer's hot air treatment, and thought Ullmann's apparatus for treating epididymitis with warm air was certainly more curious than clinically useful.

He also showed a patient from whom he had removed a keloid by means of electrolysis, according to Ehrman, with very happy results. On the first occasion he excised it under the impression of extirpating the disease, but, unhappily, it soon recurred.

#### POTENCY OF ACID FREE ALKALOIDS.

Velich, at the same meeting gave the result of his experience with non-acid alkaloids, such as nicotine, coniine, and piperidin, which were more active in raising the blood-pressure than any of the others; this he attributed to their more energetic action on the vasomotor centres, while the other substances act more on the periphery. To demonstrate this fact is no easy task, as the whole central nerve system must first be eliminated, which means destroying the life of the animal.

If 100 or 200 cubic centimetres of a physiological solution of sodium chloride be injected into the vessels on the right side of the heart immediately after removing the medulla the animal can be made to survive two hours after the operation, which was demonstrated long ago by Spina. By the help of Spina's facts Velich found that nicotine, coniine and piperidin raised the blood pressure by their peripheral action.

If any of those poisons are injected several times in rapid succession this elevated pressure is not observed, but if at this point the extract of the suprarenal body be injected the vessels are rapidly contracted, as if only one dose of poison had been injected.

Nicotine seems to act more through the vessels, while coniine and piperidin act more on the peripheral vasomotor ganglia.

The vessels of the brain, lungs, and retina were exceptions to these drugs, as some of them were contracted by the acid free alkaloids, but on the contrary the vessels of the brain were dilated. Velich cannot say he has yet discovered a drug that causes real contraction of the vessels in the lung.

Whether these drugs have another action on the

medulla oblongata and spinal cord, when *in situ* he will not venture to predict as his experiments were confined to the peripheral organs. In tying the carotid artery close to the subclavian we cannot depend upon the half of the medulla being acted on as the arterial anastomosis is too great to make the experiment of any value.

#### FACIAL PRESENTATION.

Ostreil gave an analysis of 11,513 cases delivered at the "Hebammen" Clinic of Prague, of which fifty-nine, or 0.5 per cent., were face presentations. Of these fifty-nine one-third were primiparæ, and two-thirds multiparæ. This position was no more dangerous for the mother than the vertical pole, except that labour was more protracted. Infant mortality is high, being 41.8 per cent. In six cases, or 10 per cent., instruments were used, with two fetal deaths. In one case perforation was performed; twice turned; while nine were improved by Thorn's manual correction.

Ostreil recommends the earliest possible interference to correct the position according to that recommended by Schatz, which may be easily performed if sufficiently early diagnosed and no complications present.

When the head has descended well into the pelvis, and the os fully dilated, chloroform should be given, and Schatz's method tried; failing this, Thorn's method may be undertaken, i.e., pass the hand into the uterus till the occiput is firmly grasped, which is then drawn forward while the face recedes. This operation is assisted by the second hand manipulating the external surface of the abdomen.

The cause of this position is often attributed to the dolichocephalic condition of the foetus, but Ostreil thinks this a result and not a cause. The primary cause he assigns to the great size of the foetus; in all his cases only eleven of them were under 3,000 grammes. This state shows the chin to fall low and catch on the pelvis.

## Continental Climatic Stations

[FROM OUR OWN CORRESPONDENT.]

### MURREN.

"Where Alps arise."

MURREN claims pre-eminence among the health resorts of the Berner-Oberland for beauty of position, and for unique mildness of temperature at so great an elevation. The village occupies a broad sheltered terrace 5,300 ft. above the sea-level, and face to face with the great peaks of the Jungfrau range, commanding a very near view of an incomparable Alpine panorama. On the left, across the deep valley of the White Lutschine river, the prospect is over the verdant Wengen and the stony Scheideck plateaus, with the snowy summits of the Wetterhorns behind; to the right of these is the precipitous pyramid of the Eiger and the broad snowy outline of the Monch. Yet nearer is the dark mass of the Black Monch, on which can frequently be seen chamois grazing, and above which towers the superb Jungfrau, and by its side the dazzling loveliness of the Silberhorn. Yet more to the right come, one after the other, the Gletscherhorn, Ebnefuh, Mittaghorn, Grossehorn, Breithorn, Tschingelgrat, Gespaltenhorn, Buttlaesen, each great enough in its grandeur to make any other spot notable.

The village has a mixed aspect; old-world chalets

intermingle with *fin de siècle* hotels, of which the premier for position and comfort is the Grand Hotel des Alpes. Murren is an all-year-round residence. In July and August its hotels and pensions are gay and crowded, giving an attractive, lively spectacle of Continental summer life. To many its quieter months of May and June are more attractive, for as soon and as rapidly as the snows recede, its meadows, hillsides, and woodlands are richly decked with flowers; white crocus, violet bells, gentians, anemones, auriculus, and primulas abounding all around, and making the numerous walks "things of beauty," for here Nature has placed the grand and the lovely side by side. One of these walks is to the Blumenthal, a hollow surrounded by mountains and remarkable for its wealth of Alpine flora. For the athletic the heights near Murren afford ample exercise, especially in September, when the very clear atmosphere is most favourable for mountain views.

Among the climatic advantages of Murren may be mentioned:—

1st. Its complete protection at all seasons, although at so high an altitude, by the Allmendhubel and hills further back to the north and west, from bleak and violent winds and against sudden changes of temperature.

2nd. Its very desirable southern exposure.

3rd. Its separation by a ravine-like valley, 1,600 feet in depth, from the immense glaciers and snow-covered mountains immediately *vis-a-vis* to the village. This deep valley has a peculiar beneficial effect upon the evening temperature. During the day the radiation from sun's beams on the precipitous wall of rock upon which the village is built warms the air in the valley. When the air on the heights opposite Murren after sunset becomes cool and heavy, this cooler and heavier air sinks gradually into the intervening valley, forcing up on the Murren side the lighter and warmer air which flows as a warm current over the Murren plateau; an agreeable process often noticeable in the village until midnight.

A sojourn at Murren can be recommended in cases of debility, especially for variations in the composition of blood arising from anæmia, defective assimilation, hæmorrhages, suppurations, fevers, excessive mental exertions and perturbations. It has been very successful for cachexia, malaria, and disorders caused by tropical climates; also in convalescence after pleurisy and pneumonia, in chronic asthma, dyspepsia, insomnia, and early stages of consumption when unaccompanied by hectic symptoms.

Murren is accessible from Interlaken and Grindelwald by railroad to Lauterbrunnen; thence by Funicular to Grutschalp; and thence by electric railway through pleasant fields and woods to Murren village. The water-worked Funicular from Lauterbrunnen will be changed the coming autumn into an electric line, giving greater facility of access, and enabling the Murren hotels to have an excellent winter season. Its southern exposure, equable temperature, and peculiar position will speedily make it a popular home when the change of Funicular has been completed.

HIS MAJESTY KING EDWARD VII. has consented to become the Patron of the Royal Medical Benevolent Fund Society of Ireland.

## The Operating Theatres.

### ST. MARY'S HOSPITAL.

CASE OF MIDDLE MENINGEAL HÆMORRHAGE.—Mr. H. STANSFIED COLLIER operated on a man, *æt.* 40, who had been admitted after having fallen from his bicycle on to his head. He had been picked up in an unconscious condition, but when brought to hospital he had regained consciousness. He was bleeding considerably from the right ear, and his left hand grasp was a little weak. He expressed himself as not being much hurt, and Mr. Hunt, the House Surgeon, had some difficulty in persuading him to stay in. Three hours later the patient showed a definite left hemiplegia, and very rapidly became unconscious, and had a very slow pulse. The circumstances being very urgent, three hours and a half after admission he was taken to the theatre, and Mr. Collier turned down a large flap of scalp from the side of the head, and found a linear fracture crossing the base of the mastoid process from behind forward. A disc of bone was removed from the parieto-mastoid junction, and an enormous extra-dural clot was discovered, but no tear of the dura mater. A second disc of bone was now removed at the anterior inferior angle of the parietal bone; it was then ascertained that the dura mater was separated over nearly the whole of the right half of the vault. By the aid of a suitably curved Volkmann's spoon some ounces of firm clot were removed. While this was being done sharp bleeding continued, and this was with difficulty arrested by plugging with strips of cyanide gauze which were passed down through the anterior trephine hole towards the foramen spinosum. At the completion of the operation the cavity from which the clot had been removed was still present, and there seemed to be no expansion of the cranial contents. Mr. Collier remarked that this case was an excellent example of middle meningeal hæmorrhage, and that the sequence of transient unconsciousness, recovery of consciousness, and hemiplegia, followed by a relapse into an unconscious state, was particularly well illustrated; the pouring of venous blood from the ear had made him at first a little uncertain as to the diagnosis, because he had seen a similar group of symptoms resulting from intra-dural hæmorrhage from the lateral sinus; it was on this account that he had made the posterior trephine hole. In this case, he pointed out, it was clear that a fracture of the base ran through the petrous bone into the greater wing of the sphenoid and the middle meningeal artery was ruptured very close to the foramen spinosum. Failure on the part of the cranial contents to expand was probably in part due to the condition of shock, the cardiac failure being very obvious; in addition perhaps the brain was actually buckled in towards the ventricle. To stop the hæmorrhage it might appear to be better, he said, in such a case to tie the external carotid, but the collateral circulation is so free that this procedure might not stop the bleeding altogether, and one would have the disadvantages of operating on a neck which was unprepared by antiseptics. He pointed out that the plug as he had inserted it would not be large enough to cause any serious compression, it would be removed the next morning, and in spite of the shocked condition of the patient he would hope that he would do well.

The man rallied well, and was conscious three or four

hours after the operation. Five grains of calomel were given, and some bromide of potassium to combat the restlessness. Next day the paralysis had disappeared, and the man was discharged cured in a fortnight.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 24, 1901.

### THE "LIGHT" AND OTHER TREATMENTS.

RECENTLY a sub-committee of the British Medical Association has passed in solemn conclave a resolution that it is a breach of professional ethics for any medical man to allow his photograph to be published. As an abstract resolution the standard of that decision stands high, but when reduced to practice it will, in all likelihood, sink at once to the futile level of a pious opinion. The truth of the matter seems to be that veiled advertisement finds its fullest and most skilled expression among the higher ranks of the profession. Any candid reader who thinks for a moment of the scores of photographs of professional brethren that have come to his notice in lay journals will be able to form a decided opinion not only as to the extent of the practice, but also as to the status of these victims of editorial pushfulness. But if it be wrong in principle to obtain public newspaper notice in the form of portraiture, it is clearly no less culpable for a physician or surgeon to have his name lauded in the lay journals in connection with this or that treatment. Yet this kind of thing has been going on for a year or more in connection with one of the largest of our London hospitals. We allude to the systematic press notices of the Finsen light treatment of lupus and certain other skin conditions that have appeared in the public press, together with specific and repeated mention of the names of certain medical men. To some extent the gentlemen thus invidiously selected for journalistic attention must command our sympathy in their somewhat painful position. If this sort of thing is to be permitted in high places, however, there is no reason, at any

rate on the surface, why a similar means of getting in touch with the public should not be wilfully and knowingly adopted by enterprising general practitioners. The ethical offence is the same whether committed in the West End square or the East End slum. In the case of the Finsen light treatment the facts of the case are such as to demand serious attention on the part of the medical profession and of the public. The success of the method in curing lupus is undeniable, but there is no scientific evidence either that the cure is permanent or that the results of that particular plan are better than those yielded by ordinary surgical treatment. On the other hand, the cost of the apparatus and of its administration are relatively enormous, to say nothing of the tedious nature of the process. On the whole it may pretty safely be prophesied that in a few years' time the Finsen method of the treatment of lupus will be a curiosity of medicine, just as many a therapeutic fashion has come and gone. Meanwhile the lay journalist finds material for much interesting "copy" from the complicated measures introduced by Finsen. At the same time, a matter that more nearly concerns our readers, the names of a certain number of physicians and surgeons are being noised abroad in connection with that treatment. Something of the same kind is being done in the therapeutic action of the X-rays, or rather of the focus tube from which the X-rays are emitted. There can be no doubt that the focus tube exercises a healing action upon lupus, certain forms of ulcer, and other affections of the skin. Here again, however, we are faced by the general consideration that similar beneficial results can be obtained equally well from ordinary treatment. That view of the position is confirmed by the attitude of the leading dermatologists, none of whom have seriously advocated the use of the X-ray tube in skin practice. On the other hand, we find a few medical men receiving wide newspaper notice on the score of their wonderful results with the X-rays in that class of case. Now and then, it may be well to add, some of these attempts, guided by more zeal than balanced knowledge, have resulted in serious injury to the patients. To sum up the position of the profession with regard to the light ray and so-called X-ray cures, it may be said that, for the time being, professional judgment is suspended as to their exact value, and that in the meantime it is derogatory to the medical profession as a whole, and to those medical men in particular whose names are publicly associated with those methods, that the therapeutic measures in question should receive notices in the public Press.

### THE PROPOSED NATIONAL JOURNAL OF OBSTETRICS AND GYNÆCOLOGY.

THE adjourned meeting, to elect a committee with a view to the foundation of a national journal devoted to midwifery and the diseases of women, and representative of Great Britain and Ireland,

together with the Colonies and Dependencies which complete the British Empire, will be held to-day under the presidency of Sir John Williams. Accordingly, it is of interest to ask ourselves what position will such a journal occupy, if it be founded? Questions of many kinds must occur to the minds of obstetricians and gynecologists with regard to its future. Is it required? Will it injuriously affect the interest of the various societies which already publish journals or transactions? What will be its scope? That a national journal devoted to obstetrics and gynecology is required, there is little room for doubt. Indeed it is curious that such a journal was not sooner started. But it must be a national, or rather an imperial, journal, carried out on the widest lines, well illustrated, and of large size. In fact, to take a phrase from our Transatlantic brethren, it must be a "big thing." If it is stunted in its youth, assuredly it will never get the necessary pabulum of subscriptions which it requires. A journal of gynecology and obstetrics which limits itself to the United Kingdom will have but a short life. A few years ago, such a journal might have been successful, when the newness of gynecology, and the consequent opportunities which this subject furnished for individual work were such as would have provided abundant material. Now, the newness has somewhat worn off, and the consequent yield of journalistic matter is diminished. But perhaps this in itself is an advantage. We do not want a journal in which the opinions of British gynecologists are repeated *ad nauseam*—opinions which in many cases can be readily foretold before they are uttered; but we do want a leavening up or down—as the case may be—of home opinions and doctrines by the introduction of the knowledge and opinions of our Colonial brethren. But will not such a journal interfere prejudicially with the interests of our British obstetrical and gynecological societies? There are two societies which publish Transactions, and there is one which publishes a quarterly journal. Do not these publications adequately meet the needs of the British gynecological and obstetrical world, and will not the proposed journal sap the strength of the societies by depriving them of their members? We do not think so for one moment. The proposed journal must, in our opinion, be an imperial one in order to succeed. The journal of the British Gynecological Society is devoted to the work of the Fellows of that Society, and its circulation is—save for a few copies—limited to the Fellows. It is a part of the Society, and Fellows and prospective Fellows will be no more drawn away from their actual or prospective allegiance by the fact that an Imperial journal of gynecology has been started, than are the Fellows of any medical or surgical society drawn away because there are great medical and surgical journals published. Men join a society in order to belong to that society and to take part in its debates, and not merely to obtain the published report of its proceedings, even if such a report

assumes the form of a journal. The interests of the other societies to which we have alluded—the London and the Edinburgh Obstetrical Societies—will be even less affected by the issue of the proposed journal than is the Gynecological Society, inasmuch as they publish their proceedings in the form of transactions. Consequently, we trust that *all* our British gynecological and obstetrical societies will join in furthering the establishment, and in ensuring the success of the proposed journal. No individual society can prevent the foundation of such a journal, but by withdrawing its aid and so depriving the journal of that universal support which is so necessary, it can make ultimate failure take the place of success. If the new journal goes abroad as the representative of only a section of British gynecologists and obstetricians, what hope has it of becoming truly Imperial? And upon this we lay special stress, the more truly imperial the new journal is, the less it will affect the interests of individual British societies; the more it is crippled by the lack of universal support, the more it will interfere with the interests of the societies. Space forbids us from writing more. One point we would strongly urge—that the promoters of the journal should take every step, as we believe they will take, to ensure that their journal shall be representative of the entire obstetrical and gynecological world of Great Britain and Ireland, and of our colonies and dependencies, and that if they find insuperable difficulties in the way of creating so universal a journal they will spare themselves the pain of originating a failure.

#### HERNIA OF THE URINARY BLADDER.

ONE of the commonest operations which the surgeon is called on to perform is that for the relief of inguinal hernia. As a rule no difficulty is experienced, and if the patient is in hospital the usual course is to supplement the primary operation by performing the radical cure. The operation, however, is not always one of election; it is not unfrequently one of urgency, to be performed under the most unfavourable conditions, and in a state of extreme physical prostration of the patient. To add to the difficulty it has, at times, to be done by a poor, artificial light, which is very unsuitable for making the necessary examination of the contents of the tumour. In such hernial tumours the surgeon must be prepared to meet any of the abdominal or pelvic viscera, or, indeed, almost all of them, as in the case of the distinguished patient of Cline and Cooper. One of the least frequently found of the viscera is the bladder, which is present in about one per cent. of such cases, according to Sjovall, and at all ages, from twelve months to eighty years. It is not easy to recognise the viscuseven in daylight and in artificial light the recognition is still more difficult. The experienced operator needs not to be told that the walls of the urinary bladder as seen in such a tumour may vary in thickness from that of the wall of the ileus to

that of the cardiac ventricle. A fold of peritoneum may completely or partially envelope the protruding part, or it may be wholly uncovered by peritoneum, but found adherent to a lipoma. A golden rule in such cases is to cut nothing until you know what it is. And although circumstances may require that the urinary bladder be incised—as it has been for a calculus—it is very seldom necessary to do so, and the neatest closure of an incised wound is not equal to the unwounded viscus. In all doubtful cases the diagnosis may be made by passing a catheter, and, if necessary, so raising and gently pressing the protruding part as to drive its contents into the bladder, and again passing the catheter, as recommended by Percivall Pott; there still remains the hypodermic syringe, by which fluid may be drawn off and tested. Before operation it is well to get the history of the case—in some of the recorded cases the patient found even when he had emptied his bladder a further flow of urine was caused by pressing on and raising the rupture. In Brodie's case urination was effected by lying down and raising the lower limbs and pressing on the sac, which extended almost to the knee. Petit's patient adopted a similar manoeuvre to empty his bladder. Sometimes these cysts became very large, in Clements' case pressure on the swelling produced two quarts of urine. In Percivall Pott's case and in Mr. E. S. O'Grady's the hernia was suddenly produced by violence. But this is exceptional, in the great majority of cases the protrusion of the viscus is gradually brought about, and not unfrequently the protruding part assumes an elongated form like to the appendix, for which it has been mistaken. This gradual formation of the cyst allows of the function of the viscus being carried on without any serious inconvenience to the patient, unless the cyst becomes very large, so much so that in many cases the condition has not been recognised until after death, as in the case reported in 1520 by Dom J. Sala, in which the patient had all the symptoms of stone in the bladder. The stone could never be felt by the sound, but was found after death in the bladder, which had formed a cystocele in the groin. Similar cases have been reported by Bertholin, Plateau, Bonet, Petit, Heny, Vardier, and others the majority of whom are quoted by Morgagni and by Vardier. Some few cases have recently been added which show the difficulty of recognising the urinary bladder when present. Dr. Cheesman's case (*Med. Rec.*), in which the conditions were such that he did not recognise that he had incised the bladder until he examined the sac after removal, and was disturbed to find attached firmly to it a disc of mucous membrane about as large as a silver dollar, and easily recognisable as bladder mucous membrane. In our last issue we published M. Racoviceano's two cases, one a case of femoral hernia, in which he avoided opening the viscus by confirming his diagnosis by a skilful use of the sound; and the other a case of inguinal hernia in a female. Both sexes are liable

to the condition, and it occurs at all ages. It is one of those complications of hernia which the operative surgeon must ever bear in mind. And in all doubtful cases it is advisable to utilise the hypodermic syringe for diagnosis. Where the invaginated portion of the bladder has become greatly elongated and is, if returned, likely to form a pouch in which urine may become stagnant and decompose, or form a calculus, it is good surgery to excise it.

### Notes on Current Topics.

#### Army Medical Service Committee.

SIR THORNLEY STOKER contributed an able letter to *The Times* last week on the scandalous manner in which the Irish medical schools have been denied representation on the Special Committee appointed to inquire into the working of the Army Medical Service. "Of eight gentlemen," says Sir Thornley Stoker, "who, exclusive of the President and Secretary, compose the Committee, five represent schools or licensing bodies in London, one in Scotland, and one in Ireland, the eighth being Surgeon-General Hooper, who presumably represents the Indian Medical Service." The member of the Committee who is named by Mr. Brodrick, specifically, as representing Ireland does so in virtue of as small a pretext as could be denoted by such a term. He is an Irish graduate, who attended the Galway Hospital in addition to Guy's Hospital, and who presumably has been in the Army Medical Service since he was qualified. His early connections seem to have been entirely about London. "While," says Sir Thornley Stoker in another part of his letter, "I have no doubt that he is a thoroughly capable officer, who will ably represent the Army Medical Department on this Committee, to speak of him as representing Irish schools with which he can have no connection save as a student, and not much then, is palpably absurd." What have the Irish schools done to deserve this slight? They have done what in all things Irish is a fatal bar to the receipt of justice in Government matters. They have been loyal to the Government, and have supplied them with candidates, and, what is more, with competent candidates, entirely out of proportion to the number of their students. It is a sad thing to have to write, but loyalty in Ireland does not pay—at least, if the Government can help it. The latter are so accustomed to the man and the Body in Ireland which is "agin the Government," that they have come to regard the man or the Body which is not in this blissful condition as lacking something morally or mentally, and, therefore, not to be the kind of person or thing to be encouraged. "In 1893"—we again quote from Sir Thornley Stoker's letter—"out of 891 officers 429 had Irish qualifications." "In 1896 the bulk of the Army Medical Department was composed of Irish graduates." At the present time 37 per cent. of the *personel* of the Army Medical Department are Irish graduates. And the return which has been made to the Irish schools for

furnishing these graduates is—that after many years one Irish examiner is elected, and that when a committee is appointed to investigate the causes which have led to, and the remedies for, the depopulation of the Service, one Irish representative is nominated, and he has no connection with any branch of the medical profession in Ireland—an Irish bull, as perpetrated by an Englishman, and one of the distinctly sterile genus. In addition to Sir Thornley Stoker's letter in *The Times*, we understand that the Irish Medical Schools have made strong representations to the Secretary of State for War, pointing to the importance of nominating a representative of these schools on the Committee. We hear that Mr. Brodrick has expressed his willingness to do so, if a representative can be suggested who will undertake to attend the meetings of the Committee regularly and that such a representative will be found in the person of Sir William Thomson. We do not know that there is any necessity to thank Mr. Brodrick for his concession, as it is one which will benefit the War Office more than it will benefit the Irish schools. Why the determination should require to be reached by the devious route of letters to the public Press, questions in Parliament, and letters from the Colleges to the Secretary of State would puzzle anyone outside the world of officialdom.

#### Diphtheria Antitoxin in Scarlet Fever.

DRS. WASHBOURN and Goodall, in their work on infectious diseases, published in 1896, gave it as their opinion that there are no known drugs that will either cut short an attack of scarlet fever, or, as has been alleged by some writers, prevent susceptible persons from being attacked. Referring to septic complications of this disease they mention that it is possible that the anti-streptococcal serum may be found to be beneficial. We now learn from the *Medical Record* of New York that Dr. C. H. Dalton, about two years ago accidentally discovered that diphtheria antitoxin is an excellent remedy in the treatment of scarlet fever, and it is further stated that later investigation proves that it is equally as efficacious in the prevention of this disease. Dr. Dalton seems to have been particularly impressed with the fact that after using antitoxin in a number of cases which were running a very severe course the malady assumed a mild form. Progress in therapeutics has advanced with such rapid strides that it is by no means safe to definitely deny the possibility of the usefulness of new measures. In this particular instance the difficulty of avoiding the contagion of scarlet fever is so widely recognised, and the liability to confuse the faucial affection in true diphtheria with the undoubted membranous formation that may be found in scarlet fever at once raises the question whether Dr. Dalton's cases might have been examples of patients suffering from the two infections. To arrive at a safe conclusion in this matter one would like to have the data recorded upon which Dr. Dalton founded his diagnosis,

because the "strawberry" tongue, for instance, met with in scarlet fever is also occasionally noticed in cases of diphtheria. Before the diphtheritic antitoxin, therefore, can be credited with this new virtue every care must be taken to eliminate all doubt as to whether the cases were really scarlet fever, and we would suggest that this can be done by the simple expedient of determining the nature of the infection by bacteriological examination.

#### Transfusion of Lambs Blood.

THE treatment of severe anæmia by transfusion is by no means a new idea, but the method has been recently improved upon by injecting the blood of lambs, which appears to be the least toxic for human beings, and certainly has the merit of being readily available. Improvement was obtained even in some cases of pulmonary tuberculosis, the patients gaining considerably in weight. According to Bier, in the *Munchener Med. Wochen*, the theory on which the treatment was founded is that the animal organism can accustom itself to very varied conditions. A man suffering from severe tuberculosis of both sacro-iliac synchondroses which had supplicated and broken through the skin in numerous places was given ascending doses of lamb's blood until 10 c.cm. had been injected. Smaller and smaller doses were then used, until it was found that only 1.5 c.cm. could be employed with safety. The general condition of this patient improved remarkably, and the suppuration almost entirely ceased. In four cases of lupus, all of which had been previously subjected to treatment without obvious benefit, remarkable improvement followed, but it is not possible as yet to say whether this gratifying result is permanent or only temporary. From the description of the cases it seems that the first effect of the injection was a general flushing of the face, and in the majority of the patients there was a desire to defæcate, and a large stool was usually expelled some time after the injection. Urticaria was sometimes noticed. In a large number an abnormal appetite was developed, and fever and chill, without any subjective signs of discomfort, accompanied the treatment. Most of the cases complained of a feeling of dryness in the mouth and exhibited severe thirst, symptoms which testify to some change in the physical character of the blood. The indications afforded by these experiments of Bier are certainly suggestive, and fuller details may stimulate other observers to confirm and extend the utility of his work.

#### The Executive Ability of Medical Men.

THE Governors of the National Hospital for the Paralysed and Epileptic have only lately announced that in future two of the medical staff shall have seats on the Board of Management of that institution, and this should to some extent be an answer to the narrow-minded outburst of prejudice in connection with the appointment of a physician on the

Board of the Lunacy Commission of the State of New York. There are some men in New York who apparently entertain the same opinion in regard to the executive capacity of medical men as that held and expressed by certain members of the Board of Management of the National Hospital for the Paralyzed and Epileptic, for we find the old familiar nonsense brought forward in New York that the education of physicians is such as not to fit them for the discharge of the executive duties incidental to membership of the Lunacy Commission, and they are alleged to be mentally contracted rather than expanded by their special education. It is almost absurd to have to argue this matter seriously, but a very good answer can be found in the disorganised condition of Bellevue Hospital which can be shown to be due to the want of medical control in the choice of the attendants. With proper medical control it would have been impossible for any such terrible state of affairs to have existed in the detention wards for the custody of insane persons or alcoholics picked up in the streets of New York. No medical man would have permitted unskilled persons without adequate instruction or proper supervision to have had the care of this most difficult and trying class of patients. It cannot be too clearly understood that no medical institution can permanently prosper whose Board of Management is excluded from the judiciously exercised influence of the medical staff.

#### The Parasitic Theory of Cancer.

THE results which have up to the present been recorded of the investigations and observations now being carried out point to the conclusion that the parasitic or infectious theory of cancer is the only one which in any way satisfies the requirements of the pathologist and the clinician. For a very long time past the relation of irritation and traumatism to cancer formation has been discussed, and modern medical literature abounds in references to the fact that malignant growths often follow local injuries and local irritations. Arguments by analogy can be adduced in favour of this parasitic hypothesis from the tumours in trees and plants which are so well known to botanists. These tumours, which are sometimes spoken of as tree cancers, are caused almost invariably by a species of infection entering from without by means of some laceration of the protective covering or bark of the tree. Mr. Jonathan Hutchinson has described how a certain fungus is apt to destroy fir trees on a large scale by inducing decay of the medulla of the wood. The condition affects the stem of the tree, which stops growing and dies, when it is found that the fungus growth has undergone decomposition not due to chemical action. In these cases there is often no traumatism to the bark to indicate the source of infection, but it is believed to enter near the roots through the agency of rodents such as rabbits. The rabbit burrows under the fir tree, nibbles the root, and thus exposes the abraded por-

tion to the action of the spores of fungi. A very curious point in connection with this fungus life in trees and plants is that it is capable, under certain circumstances, of exhibiting almost indefinite periods of latency. The recently published monograph by Max Schuler embodies powerful argument in favour of the view that cancer is due to an extrinsic cause, that is to say, has a parasitic infectious origin.

#### Tendon Transplantation.

THE great strength and preponderating influence of the flexors of the thigh contribute to make contracture of the knee a not uncommon affection, and an unfortunate circumstance which accompanies the trouble is that the condition is very intractable and often as painful as it is disabling. The principle of tendon transplantation which has proved itself so useful in other regions has been applied by Heusner to the knee-joint. According to the results published in the *Deut. Med. Woch.*, for May 30th, Heusner has succeeded in obtaining excellent functional results, the pain so frequently noticed in these cases of contracture being relieved, and the disabling deformity corrected. The muscles most available for the purpose are the biceps on the external side with the gracilis and semitendinosus on the inner side, and final success is more certain of attainment if the incisions through which the tendons are dissected out are made ample and carried half-way up the thigh so that the structures to be freed may be freely liberated from surrounding parts; after this they should be subcutaneously drawn into another incision in the patellar region through which they are sutured to the quadriceps tendon. This surgical procedure is evidently an operative method that has a wide sphere of usefulness in front of it, and will be sure to find many adherents.

#### Fatality at a Hypnotic Exhibition.

THERE is a large section of the public who flock to exhibitions by so-called "professors" of hypnotism, and sit through the usual disgusting performance of seeing the wretched "subjects" devour filth under the impresson that what they are eating is sweet and toothsome. We are glad to put on record that one of these "professors" has been put under arrest concerning the death of a "subject" who was lately killed during the performance of the feat of resting the head and the heels on the backs of two chairs with a 600lb. stone on the abdomen which it was pretended a blacksmith broke to pieces with a sledge-hammer. The cause of the fatality was the slipping of the chair away from the head of the "subject," who thus fell to the floor head first, and the stone, rolling on his head, crushed it. It must be obvious that this particular performance is characterised by fraud, and the stone which is apparently broken with such violence by the sledge-hammer of the blacksmith must, as a matter of fact, be previously broken up and cleverly pieced together for the purpose of deception. The only effective method of dealing with the debased curiosity

that finds pleasure and even mirth in the contemplation of the infirmities of these wretched "subjects," must be by educating people to a higher ethical standard, and this, unfortunately, is a long and uncertain process.

#### Undesirable Prosecutions.

UNLESS there be very good reason for suspecting deliberate evasion of the law on the part of medical practitioners in regard to the notification of infectious diseases, it is unquestionably bad policy to institute police proceedings for mere failure to notify. It is open to everyone to overlook the infectious nature of the illness, or it may be simple oversight. In the first event the law does not require a practitioner to do more than act to the best of his ability, and in the second it would, in most instances, be sufficient to warn the forgetful practitioner. These remarks are prompted by the report of some abortive proceedings brought against Dr. Harry Whittome, of Camberwell, for neglecting to notify a case of scarlet fever. The defence set up was that at the time there was no reason to suspect that the illness was of that nature, and eventually the summons was dismissed. Had the authorities taken the trouble to apply to Dr. Whittome for an explanation, no doubt a satisfactory one would have been forthcoming, and much vexation and trouble would have been obviated. We trust this and one or two other cases of a similar kind which have come before us within the last few days will impress upon sanitary authorities generally the fact that there is nothing to be gained and much to be lost by reckless prosecutions.

#### Reciprocity with Italy.

THE profession in Italy do not appear to have received the news of the step taken by the Privy Council in regard to the recognition of Italian practitioners in this country with the enthusiasm one might have expected. We must not, however, disguise the fact that the advantages of reciprocity are vastly in favour of British practitioners, so many of whom practise, or may be desirous of practising, in that country. Moreover, provided that there is *de facto* reciprocity, it matters little what the profession in Italy think of the matter. There is always, even in this land of liberty, a minority of narrow-minded persons who are unreservedly wedded to protectionism, though the application of these views to the practice of such a calling as medicine is absurd and indefensible.

#### False Teeth for Paupers.

THE plight of an elderly pauper whose teeth have "gone by the board," and who is thereby deprived of the ability to masticate the not over succulent food which boards of guardians supply, is one which may well appeal to the charitable. To ask that all the inmates of our workhouses whose denture is defective should be supplied with substitutes would be to add considerably to the burden under which ratepayers groan. Occasionally a compassionate board of guardians goes the length of

ordering a set for some specially deserving or unhappy inmate, and we note with sympathy and approval that the guardians of Abingdon have established a precedent in this direction. It would be more to the point if a scheme were devised whereby the aged and indigent poor could be supplied with artificial teeth by a local charitable agency working in concert with the dentists of the neighbourhood. A working set of teeth is almost as necessary as a wooden leg or a pessary, and fully as conducive to comfort and health. The inmates of workhouses do not exclusively belong to the worthless and improvident; they are but too often persons who are compelled by hard circumstances to wind up a life of unremitting toil in the chilling atmosphere of the poor-law, and they merit our compassion.

#### An Ineligible Antivaccinationist.

IN spite of all the influence that has been brought to bear, the Local Government Board has adhered to the view that an antivaccinationist is not eligible for the post of medical officer of health, and Dr. Scott Tebb's appointment stands annulled. Certainly, if there be one post more than another in which men with cranks would be out of place it is that of medical officer of health. He is brought into daily contact with the local practitioners, without whose cordial co-operation it would be quasi-impossible for him to fulfil his manifold duties, and there are plenty of sources of friction without importing one so peculiarly objectionable to the majority of medical men as a hostile attitude towards vaccination. Moreover, what would be such an officer's position in the event of an epidemic of small-pox? Would he sink his most cherished convictions and go in unblushingly for vaccination, or would he discourage the practice as far as he could? We do not want cranks in any department of public life, for wherever they are they lead to endless loss of time and temper by attaching undue importance to what are more often than not insignificant details.

#### Still More Penalising of the Medical Profession.

LAST week we drew the attention of our readers to a proposal by Sir Fortescue Flannery, M.P., to add a clause to the Factory and Workshop Acts Amendment Bill, whereby the medical attendant in a case of suspected anthrax shall be obliged to take a specimen of blood from the patient and send it for microscopical examination to some "bacteriological expert." We pointed out the heartless and extraordinary character of the proposal, to do this contrary to the wishes of the patient and his friends, with the patient possibly *in extremis* . . . the whole proceeding being useless so far as benefiting the patient or diagnosing his case. We trust that it will suffice to have called attention to the proposed enormity to ensure its rejection. We have now to record a further most objectionable proposal by Sir F. Flannery. He has proposed a clause in the same Bill to make it obligatory on the practitioner to notify any injury in-

curred in a factory or workshop. Here, again, we have the enforcement of penal obligation against medical men to work for the State, against which we protest. Moreover, the work here demanded is not professional work at all, for how can a medical man say where an injury was inflicted unless he was present? Must he take the word of the patient, and relying thereon sign a certificate that the man was injured in somebody's factory or workshop? The thing is too ridiculous, and Sir Fortescue Flannery is doing himself an ill service by proposing such impossible and useless amendments. Not the least offensive part of this amendment is Sir Fortescue Flannery's idea that medical men in performing this offensive task should be classed with every herbalist or impostor who may apply a piece of sticking plaster to a cut finger, which treatment would come under the surgical aid referred to in the clause. The quack and the medical man are alike referred to as under obligation to certify. We trust the profession will combine and once for all put a stop to these encroachments on the rights and privileges they should enjoy. It is certainly a hardship that the attempts to subject the profession to further indignities should be going on secretly in committee-rooms of the House, only to be discovered by accident.

#### The Housing of the Working Classes.

AN important discussion upon the housing question took place in the Commons in the course of the debate on the Vote for the Local Government Board. Several important points were brought forward. Perhaps one of the most striking was the fact that the London County Council charged from 5s. 6d. to 7s. 6d. a week for one room, from 8s. to 10s. for two rooms, and from 10s. to 12s. for three rooms. Rents of that kind are clearly prohibitive for the very poor, and show that there is some flaw in the present system. It was suggested in the House that the land values required drastic treatment, in answer to which Mr. Long answered on behalf of the Local Government Board that to treat land separately from buildings would require fresh legislation. That attitude is so far encouraging in that it recognises the need of some reform in the direction indicated. So, too, with the proposed extension of time for repayment of loans by local authorities. Mr. Long advanced certain principles of the utmost importance. As trustee for a posterity that could not be consulted, but would have to pay the bill if presented at a postponed date, he said that municipal Corporations would have to show the most rigid economy with regard to the purchase of land and the sufficiency of the buildings they erected. Other remarks of the right honourable gentleman revealed a hitherto unsuspected sympathy with advanced liberal opinion on this great social question. The extension of the period of repayment from fifty to one hundred years is regarded in the most diverse ways by different investigators. At the Ipswich meeting of the British Medical Association it was rejected by

vote of the State Medicine Section, on the ground, apparently, that any reduction of rent gained thereby would be too small to be of practical value. In the Commons Dr. Macnamara stated that the granting of the longest statutory period for repayment now permissible would enable the Council to reduce rents by 3d. or 4d. a week. The statutory limit of sixty years has been reduced in practice to forty by the Board, as against a proposed extension to 100 years, as in Prussia. The latter extension could not fail materially to reduce rents. It is really time that this point, which is capable of mathematical demonstration, should be settled definitely once for all.

#### A Judge on Doctors' Bills.

THE large percentage of bad debts made by medical men in general practice affords a striking testimony to the readiness with which they respond to the call of suffering. At the same time it testifies to the extreme unreadiness of a great majority of the public to recognise the value of services rendered by the payment of the fees that have been incurred on account of medical attendance. It is an undoubted fact, for instance, that many a busy medical man is unable to take a holiday because he cannot collect debts owing in many cases from folk who are ready to live up to their incomes in ways that do not fall under the heading of the necessaries of life. The sordid side of human nature is nowhere more grimly disclosed than in county court proceedings for the recovery of medical debts. In hearing such a case recently, Judge Owen, in a South Wales court, remarked to the defendant:—"The last person you think of paying is the doctor, and when you are ill you fall down and worship him, but when he sends in his bill you don't pay it." It would be well if this vigorous, if somewhat homely, criticism were circulated widely among the multitudinous class which seems to think that the maxim, "Virtue is its own reward," was specially framed to adjust the relations of patient and medical man.

#### More Arsenic in Liverpool Beer.

THE year 1900 should be marked with the blackest of letters in the annals of the brewing trade, for there can be little doubt that the disastrous outbreak of arsenical beer poisoning in the North of England has dealt a lasting blow against the popularity of beer. After all the outcry, the exposure of a long roll of injury and death, and the subsequent prolonged series of judicial prosecutions, it seems hardly credible that a Liverpool publican should still be selling arsenical beer. That such is the case, however, was proved a week or two ago before the local Stipendiary, who imposed a fine of £10 and £5 15s. 8d. costs upon a publican for the offence mentioned. The analyst at Somerset House found the incriminated beer to contain one-seventieth of a grain per gallon. The Stipendiary, Mr. Stewart, did not think the Act was intended to apply to a case of that kind, "where things had not been deliberately put in for the pur-

pose of making an inferior article equal to something it was not." With every sympathy for that legal opinion, we may perhaps be pardoned for congratulating the public that an Act of Parliament may sometimes protect their lives by departing from the intention of its framers. For a Liverpool publican to be still selling arsenic to his customers is simply to fly in the face of Providence.

#### The Contagiousness of Alopecia Areata.

THE contagiousness of that form of circumscribed baldness known as *alopecia areata* has long been the subject of discussion in dermatological circles. It has been obstinately denied by competent observers over and over again, in spite of the fact that it certainly tends to occur in epidemic form in regiments and schools. The obvious conclusion is that the divergence of opinion arises from the observations of the various investigators having borne on diseases similar in clinical appearance but differing in their pathological cause. The balance of skilled opinion at the present time appears to be in favour of a certain degree of contagiousness, but it is conceded to be unnecessary to insist upon the same stringent precautions as in the case of ringworm. It is sufficient in a general way to keep the infected areas covered with a dressing of some sort, and to avoid the promiscuous use of brushes, towels, &c. It is important that this view should be made generally known, because the affection is one, which runs an exceedingly protracted course and if isolation be insisted upon its successful treatment necessitates so prolonged an absence from school or factory as to cause much inconvenience and, it may be, suffering.

#### The Queen and the Nurses.

HER MAJESTY has always taken the keenest interest in nursing questions, and gladly avails herself of every opportunity to testify to her continued interest in the welfare of these handmaids of medical benevolence. On Friday last Her Majesty received a large number of members of the Royal National Pension Fund for Nurses at Marlborough House, to whom she presented their certificates of membership. Over a thousand nurses put in an appearance, and the weather being fine the reception was a great success, many of them affording, says the *Times* correspondent, ocular demonstration that the art of making millinery attractive is not incompatible with the practical requirements of a hospital costume.

#### Death of Miss Ormerod.

THE death of Miss Ormerod, the distinguished entomologist, deprives us of one of the most assiduous and devoted students of insect life, especially in its agricultural bearings. The deceased lady manifested a passion for the study from her earliest infancy, and the services which she has rendered to agriculture are quite inestimable. By the attentive study of their lives' history she was enabled to detect the insects which were responsible for the damage to crops, and to suggest means of circumscribing their

ravages. Miss Ormerod died, after a long and honourable career, on Friday last, from cancer of the liver, at her home at St. Albans.

#### The Congress on Tuberculosis.

THE labours of the Congress are now in progress. Already on Saturday the reception rooms at the Queen's Hall were thronged by applicants for registration, and again on Sunday crowds, largely composed of foreigners, besieged the offices. The labour of registration proceeded rapidly and smoothly, and each member was presented with a list of members and delegates, a programme of the proceedings, scientific and social, together with a bulky volume, being the descriptive catalogue of the Museum, reaching to close upon two hundred pages. On Monday the Congress was formally opened by H.R.H. the Duke of Cambridge at the request of His Majesty the King, at the first general meeting which took place at St. James's Hall, in the presence of a larger audience than the hall could conveniently hold. Yesterday (Tuesday) the sectional work commenced, and the second general meeting took place, when an address was delivered by Professor R. Koch, of Berlin. So far as numbers go the Congress bids fair to be a phenomenal success, and, judging from the titles of the papers, the discussions promise to be worthy of the occasion.

#### The Portrait Advertisement.

THERE exists a not unnatural confusion in the minds of the public between the General Medical Council and the British Medical Association. This is of some importance, because the two bodies occupy a very different position in regard to the profession. A clearer understanding of this fact would have cut short much correspondence and editorial comment in the lay press on the prohibition of medical men allowing their portraits to be published in lay journals, a practice which is eminently unethical. If it could be shown that the publication took place with the consent, or at the behest, of the practitioner, the Council might possibly have something to say to it; but as conclusive evidence of consent must necessarily be exceedingly difficult to obtain in such cases, the Council has, so far, taken no action.

#### Doctor v. Medical Guardian.

A NICE little problem is awaiting solution at the hands of the Newton Abbot Board of Guardians. It seems that Dr. Culross, the medical officer of the workhouse, has taken umbrage at the conduct of Dr. Ley, one of the guardians, who, he alleges, systematically inquires into the cases in the infirmary, and occasionally challenges the diagnosis and treatment, in the course of his visits as guardian. If such be really the case, Dr. Ley's conduct would be deserving of the gravest censure, and would, in fact, constitute a serious abuse of his position as guardian. The subject is under investigation, and we hope it will turn out that the allegations have no more serious basis than nurses' gossip.

### Traumatic Scarlatina.

THE occurrence of scarlet fever in a patient after an injury has suggested to Dr. Lippmann the possibility of the germs of infectious diseases lying latent in the organism ready to become active under certain circumstances. This is by no means a new theory, but the difficulty of proving conclusively that the case is *propter hoc* and not merely *post hoc* is practically insurmountable, and, moreover, the number of well-authenticated cases is far too limited to corroborate the theory, which is in opposition to all that we know concerning the genesis and natural history of such diseases.

THE King held an Investiture at Marlborough House on the 16th inst., when the honour of Knight Commander of the Royal Victorian Order was conferred upon the following gentlemen:—Sir Thomas Smith, Bart., F.R.C.S.Eng.; Deputy Surgeon-General Henry Julius Blanc, and Mr. William Henry Bennett, F.R.C.S.Eng. The following gentlemen were invested with the Insignia of Commanders of the Order:—Mr. Donald William Charles Hood, M.D., Cantab.; Mr. John Hammond Morgan, F.R.C.S. Eng., and Mr. Charles Arthur Morris, F.R.C.S.Eng.

AT the competitive examination held last month for sixty resident medical officers (*internes*) in the Paris hospitals, two of the successful candidates were women, Mesdemoiselles Arviset and Bonnet, both M.D. of Paris.

### PERSONAL.

MR. J. W. DOWDEN, M.B. C.M., F.R.C.S.Ed., has been appointed Assistant-Surgeon to the Edinburgh Royal Infirmary.

THE EARL OF DERBY will take the chair at the dinner to be given to the foreign vice-presidents and delegates to the Congress on Tuberculosis at the Hotel Cecil on the 26th inst.

SIR FRANCIS LAKING, Physician in Ordinary to the King, has been elected consulting physician, and Mr. T. Pickering Pick, F.R.C.S., consulting surgeon, to the Victoria Hospital for Children, Chelsea.

DR. J. J. B. MACLEOD, Demonstrator of Physiology in the London Hospital Medical College, has been awarded the Mackinnon Studentship by the Council of the Royal Society, for the purpose of enabling him to carry on researches in pathological chemistry.

ONE by one the many appointments held by the late Mr. Thos. Bond, F.R.C.S., are being filled, the last being by the Secretary of State, who has appointed Dr. John Norton, surgeon to the A Division of Metropolitan Police attached to Great Scotland Yard, Westminster.

MR. G. L. DRUCE, M.A., F.L.S., Mayor of Oxford, President of the British Pharmaceutical Society, will preside at the annual Conference, to be held this year in Dublin on the 29th, 30th, and 31st inst. The Lord Mayor of Dublin will welcome the members of the Conference, the meetings of which will be held in the rooms of the Royal Dublin Society.

### Scotland.

[FROM OUR OWN CORRESPONDENT.]

SLANDER ACTION AGAINST A GLASGOW DOCTOR.—A case presenting some very painful and even discreditable features has just been before the Court of Session in Edinburgh. A Mrs. Wallas, with consent of her husband, Joseph Wallas, jun., 72, Preston Street, Govanhill, Glasgow, raised an action against Dr. James W. Wallace, residing at 87, St. Andrews Drive, Pollokshields, for £500, as damages for alleged slander. The pursuer has a son, aged two years, who for a year had been under treatment by a Govanhill doctor. The defender in February last was consulted regarding the child's condition, and at his request he was repeatedly consulted. He informed the pursuer that the Govanhill doctor's diagnosis was wrong, and the treatment was, therefore, wrong, and had aggravated the child's ailment, and if continued the child would not long survive. Later on the defender informed the mother that he had seen and consulted with the Govanhill doctor, and had pointed out to him the errors in the treatment. He also informed her that the Govanhill doctor had often to make use of his assistance in difficult cases. The pursuer learned from the Govanhill doctor that the defender's statements were absolutely false, that he had no meeting with the defender, and that the defender had never been consulted by him in any case. Dr. Duncan, of the Victoria Infirmary, confirmed the diagnosis, and approved of the treatment carried out by the Govanhill doctor. The pursuer's statements were embodied in a declaration made before a Justice of the Peace, and the matter was then brought before a committee of the Southern Medical Society, of which both doctors were members. Before this was done an opportunity was given the defender of explaining his position. He then stated that the pursuer's declaration was false, and it is alleged he called her a liar, and made other statements relating to the pursuer and her family which were derogatory. In Court the defender's counsel asked that the reference to what had taken place before the committee of the Southern Medical Society should be struck from the record. The judge declined to do this, and rightly so. The case has been settled by the defender paying £101 and expenses. Evidence has not been led in this case, but the fact that the defender has tendered such a payment as the above would naturally lead one to infer that the serious allegations were in some measure at least true. That being so, the case is a very bad one indeed, and anything but creditable to the defender. It would be interesting to the profession at large to know what took place before the Committee of the Southern Medical Society. Without entering into detail, we venture to suggest, if such allegations are true, that it is perhaps the duty of a Society to ask for the resignation of a member who could be guilty of such conduct.

WILL OF DR. JAS. DUNLOP, OF GLASGOW.—The will of the late Dr. James Dunlop, 16, Carlton Place, Glasgow, has just been lodged with the Sheriff Clerk of Lanarkshire. It amounts to £20,849 16s. Dr. Dunlop, although well advanced in years, volunteered for active service in South Africa at the beginning of the war, and for some time was attached to the hospital at Wynberg. Soon after his return to Glasgow he began to complain, and died a few months ago.

### Scarlet Fever in Birmingham.

THE Health Committee of the Birmingham City Council are much disturbed by the serious prevalence of scarlet fever and additional accommodation is urgently required. For some weeks past the average weekly number of cases has been 238, with a weekly average in hospital of 344, that is to say, 100 more than the average for last year. It is unusual for scarlet fever to assume an epidemic form so early in the year, and the committee are not unnaturally anxious as to what will happen should the normal autumnal increase in the returns be superadded.

## Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

## "HIGHER" DENTAL DEGREES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The announcement in your editorial notes to-day (July 17th) that the University of Birmingham has decided to institute a new degree to be styled "Bachelorship of Dental Surgery," will, I believe, come as a surprise to most of your readers practising in that speciality, and I venture to affirm that if those dental surgeons who have valid claim to speak with authority on professional questions could be polled an overwhelming majority would be found to agree with you in denouncing the step as unnecessary, uncalled for, and likely to prove as injurious to the dental branch as to the whole medical profession. The licence in dental surgery forms a first-rate special qualification. Students who have conscientiously worked through the curriculum and passed the examinations are probably better prepared for the pursuit of their calling than the votaries of other specialities for whom no special training is provided by the authorities, and who are left to their own devices.

Extra courses of anatomy, physiology, or other medical subjects will not make the dental licentiate one jot better as a practitioner, nor will a "higher" degree based on a little knowledge of that kind advance the "bachelor of dental surgery" in the estimation of his professional brethren. The first thing is to become an accomplished dentist. After that, if higher professional position is sought for, the proper course is to take degrees in arts, science, or medicine; and this is what an increasing number of dental candidates now strive for. A fair proportion of the younger generation of dentists are now graduates in arts or science of one or other university; and many of them hold medical or surgical qualifications. These are the "higher" degrees which are valuable to the individual in making him a broadly-educated professional man, standing in wealth of general culture and in special knowledge on a level with practitioners of other departments of medicine. This status he will not be able to claim from a degree of the kind described in your note. It is certainly astonishing that the University of Birmingham, which everybody has understood was to have been above all things a pattern of practical sound sense, should have lent itself to the promotion of a scheme so crude, so valueless, and even injurious.

I am, Sir, yours truly,

A PAST PRESIDENT ODONTOLOGICAL SOCIETY.

July 17th, 1901.

## THE CHELTENHAM MEETING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall esteem it a favour if you will state in your next number that there will be a meeting of members of the B.M.A. interested in its reform, on Monday evening, July 29th, at 9 o'clock, at Cheltenham, to discuss the proposals of the Reconstitution Committee, notably with regard to co-optation by the Council, the Referendum, and Finance. The place of meeting will be duly announced by circular. The object is to decide upon the attitude to be adopted on presentation of the report to the annual general meeting.

I am, Sir, yours truly,

JAMES BRASSEY BRIERLEY.

Alma House, Old Trafford.

## A Chemist-Apothecary Fined.

MR. W. M. JENKINS, a chemist at St. Clears, Carmarthen, was fined £20 last week for practising as an apothecary. It was proved that he had examined patients and then prescribed for them, this having transpired at the inquest on one of his patients who had died. The defence was that he had charged for the medicine supplied and not for the advice, but this fiction did not find grace with the jury.

## Literary Notes and Gossip.

A NEW series of articles dealing with the practical side of microscopy, together with notes and queries, correspondence, and description of new apparatus are appearing each month in *Knowledge*, under the editorship of Mr. M. I. Cross, joint author of the well-known hand-book, "Modern Microscopy."

ANY announcement of a new work from the pen of so brilliant a surgeon as Prof. Mayo Robson is of interest to the profession. He has now in the press a work on "Diseases of the Stomach and their Surgical Treatment," in the production of which he has been assisted by Mr. B. G. A. Moynihan, F.R.C.S., Arris and Gale Lecturer on Surgery, Royal College of Surgeons. Messrs. Baillière, Tindall and Cox will be the publishers.

As previously noted in these columns, a proposal has been put forward having for its object the foundation of a new monthly *Journal of Obstetrics and Gynaecology*. A meeting was held last month in the rooms of the Medico-Chirurgical Society of London and adjourned until today (Wednesday) at 5 p.m., when it is proposed to elect a committee of "ways and means."

DR. SOLOMON SOLIS COHEN, A.M., M.D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic, is engaged in editing a "System of Physiologic Therapeutics" by American, English, French, and German authors. The work will be complete in eleven volumes, and will be published by Messrs. P. Blakiston's Son and Co., Philadelphia.

SACHS and Brooks think that much can be done to record the progress of cases of muscular dystrophy. They report several cases in the *American Journal of the Medical Sciences* for July, in which great benefit accrued from systematic muscular exercises. Scudder describes, in the same journal, a case of a supernumerary ureter ending blindly, causing acute abdominal symptoms in a child, aged twenty months. This is only the ninth recorded case.

THE new "Text-book of Military Hygiene," by Surgeon-Capt. Munson, is, we hear, attracting considerable attention in army medical circles. Founded as it is on modern warfare, and dealing fully with future requirements in connection therewith, it is necessarily of a revolutionary character when compared with the old standards. But the recent American-Spanish war and the present Boer conflict have punctuated inherent defects and made reforms necessary.

"THE Belfast Health Journal" is one of the latest aspirants for public favour, and it has gone the right way to secure it by giving an excellent series of articles on its speciality and numerous good illustrations, also for traits of worthy health pioneers and philanthropists, of whom Belfast contains many, some being of worldwide repute as generous donors and sagacious philanthropists. Our contemporary has commenced well, is deserving of success, and we have little doubt that it will be attained.

THERE are not many new books in medicine usually issued during the dead season, but the publication of another edition of Rose and Carless's "Surgery" has been rendered necessary because of the rapid disposal of the previous edition, for which reason also the new volume will be little more than a reprint, with corrections to date. New editions are also announced as ready in a few days of Mr. de Méric's "Syphilis and other Venereal Diseases," and of Dr. Macnaughton-Jones's "Practical Points in Gynaecology."

WE are reminded of the steady flight of time by the appearance of Vol. CXXIII. of "Braithwaite's Retrospect of Medicine." This last half-yearly volume is full of the usual interest, and no man who wishes to keep abreast o-

professional matters, whether general or special, can afford to be without this most trusty old friend upon his bookshelves. It is not too much to say that the whole series of volumes, ranging as it does over sixty years, contains the history of medical progress during that remarkable period of scientific progress and enlightenment. It is to be hoped that Braithwaite's will thrive vigorously into an age not less prolonged than that attributed to the wandering Jew of fable.

LITTLE that is new can be said by way of description of that attractive health resort, Carlsbad, sometimes termed the "Mecca of Europe," because of the thousands who journey there for the *healing waters* year after year. Apart from its attraction for invalids, the town, rising as it does in terraces among the pine and fir clad hills, is extremely picturesque and well deserving the encomiums passed on it by artists and travellers. To make it still better known to English folk the Municipality of Carlsbad have just issued a volume of about 200 pages, edited by Dr. Josef Ruff, which they present gratis to visitors, or will send on application to anyone intending to visit the spot. In this book will be found descriptive and pictorial accounts of the various springs, bathing establishments, excursions, travelling routes, hotels, expenses, &c., so that a little optical and mental labour is all that is necessary.

THE "Atlas of the Anatomy and Physiology of the Child," with explanatory text by D'Arcy Power, M.D. Oxon, F.R.C.S., displays, in the superimposed, pictorial form, the special features of child anatomy, in the manner which has long since become familiar to students of the well-known series published by Messrs. Baillière, Tindall and Cox. The text is evidently designed for popular consumption, and is written in simple, untechnical English, suitable for the purpose, and it would be well for future generations if the mothers of to-day could be induced to follow its teaching. Some people, probably the large majority, are satisfied with a remarkably small acquaintance with the details of their anatomy and the play of their functions, but there are others who yearn to know something of the wonderful organism of which they are the temporary possessors. To such this Atlas will be welcome, for with a minimum tax upon the intelligence it illustrates the mechanism and its component parts. At three shillings—the price thereof—such knowledge is now placed within the reach of all.

#### NEW BOOKS AND NEW EDITIONS.

The following has been received for review since the publication of our last monthly list:—

- BAILLIÈRE, TINDALL, AND COX** (Henrietta Street, Strand, London).  
 The Theory and Practice of Military Hygiene. By Surgeon-Capt. E. L. Munson, M.A., M.D. Pp. 971, with 8 plates and 400 engravings. Price 32s.  
 Manual of Public Health, Laboratory Work, and Food Inspection. By O. W. Andrews, M.B., M.R.C.S., D.P.H.Camb. Pp. 292. Price 7s. 6d. net.  
 The Commonwealth of Cells. By H. G. F. Spurrell, B.A. Oxon. Pp. 126. Price 2s. 6d.  
 An Atlas of the Anatomy and Physiology of the Child. By D'Arcy Power, M.B., F.R.C.S. Price 3s.  
**BALF, SONS, AND DANIELSON, LIMITED**, (London).  
 The Association of Inguinal Hernia with the Descent of the Testis. Bradshaw Lecture. December, 1900. By John Langton, F.R.C.S. Pp. 68. Price 5s.  
**CHURCHILL, J. AND A.** (Great Marlborough Street, London).  
 St. Thomas's Hospital Reports. Vol. xxviii. Price not stated.  
 Schoolboys' Special Immorality. By Maurice C. Hime, M.A., LL.D. Third Edition. Price 1s.  
 The Ophthalmoscope, a Manual for Students. Fourth Edition. By Gustavus Hartridge, F.R.C.S. Pp. 152. Price 4s. 6d.  
**CHARLES GRIFFIN AND CO** (London).  
 Outlines of Diseases of Women. By John Phillips, M.A., M.D. Cantab., F.R.C.P. Third Edition, revised. Pp. 280.  
**LEWIS, H. K.** (Gower Street, London).  
 Purulent Nasal Discharges: their Diagnosis and Treatment. By Herbert Tilley, M.D., &c. Price 4s.  
**MACMILLAN AND CO., LIMITED** (London).  
 Anæsthetics and their Administration. By Frederic W. Hewitt, M.D. Cantab. Second Edition. Pp. 528. Price 15s.  
**SCOTT, GREENWOOD AND CO.** (London).  
 Practical X-Ray Work. By Frank T. Addyman, B.Sc., F.I.C. Pp. 300, with 12 plates. Price 10s. 6d. net.

**SIMPKIN, MARSHALL, HAMILTON, KENT AND CO. LIMITED** (London).  
 The Half-yearly Retrospect of Medicine. Vol. 123. Edited by James Braithwaite, M.D. Lond., and E. F. Trevelyan, M.D. Lond., F.R.C.P. Pp. 467. Price 6s. 6d.

**SMITH, ELDER AND CO.** (London).

A Retrospect of Surgery during the Past Century. By John Poland, F.R.C.S. Pp. 97. Price 5s.

**S WAN, SONNENSCHNEIN AND CO., LIMITED** (London).

A Treatise on Plague. By Major Geo. S. Thomson, M.B., M.A.O. Roy. Univ. Irel. Pp. 299. Price 7s. 6d.

**WRIGHT AND CO.** (Bristol).

Golden Rules of Hygiene. By F. J. Waldo, M.A., M.D. Cantab. Pp. 69. Price 1s.

### Literature.

#### FREYER'S STRICTURE OF THE URETHRA. (a)

THE author of this volume states that it consists of a series of lectures which he delivered at the Medical Graduates' College and Polyclinic in November last, and that he has published them in book form at the suggestion of many of his hearers.

The book contains six lectures, three of which deal with stricture of the urethra and its treatment, and three with enlargement of the prostate and its treatment.

Mr. Freyer's method of dealing with his subject is clear and concise; every lecture shows that he has a thorough grasp of the practical side of what he is writing about, and the treatments advocated are those which have been thoroughly tested by himself and many others. Of course there are some few points which may not please everybody, such as his classification of strictures, his evident hankering after the malarial origin of many cases of urinary fever, and his advocacy of vasectomy in the treatment of severe forms of prostatic enlargement.

Very properly the author does not write his lectures to advocate any fads of his own, and the practitioner who treats his patients according to the directions given will treat them well, and the surgeon who reads these lectures will, when next lecturing his hospital class, give a clearer and more concise account of modern urethral surgery than he would if Mr. Freyer had not given us this very excellent little book.

#### WANKLYN'S ARSENIC. (b)

PROF. WANKLYN may well claim to have been a pioneer in the methods of chemical analysis, and although a veteran in the world of chemical literature his energy and enthusiasm is still unabated, as evidenced by this excellent and most timely little work, which, as the author indicates, "has been called forth by the recent mysterious epidemic of chronic arsenical poisoning in Manchester, Liverpool, and other towns in the North of England." The outbreak of peripheral neuritis and other manifestations of arsenical poisoning have very rightly attracted the attention of all sorts and conditions of men, but the medical and chemical aspects have given rise to much discussion and will afford matter for extensive investigation. A book, therefore, such as the present, is in every way opportune, and its perusal cannot but prove helpful and highly suggestive.

The chemistry of arsenic is first carefully dealt with, the characters of arsenic both in the free and metallic state, and also in the form of arsenious and arsenic acid, and their salts fully detailed, and interesting reference is, moreover, made to the organo-metallic compounds of arsenic and kakodylic acid and its salts.

The methods for the detection and measurement of arsenic are dealt with at length. Such various views

(a) "Stricture of the Urethra and Hypertrophy of the Prostate." By P. J. Freyer, M.A., M.D., M.Ch., Surgeon to St. Peter's Hospital, London, Lieut.-Colonel, Indian Medical Service (Retd.). London: Baillière, Tindall, and Cox. 1901. Demy 8 vo, pp. 115. 40 illustrations. Price 5s.

(b) "Arsenic." By J. Alfred Wanklyn, M.R.C.S., formerly Lecturer on Chemistry and Physics at St. George's Hospital, Professor of Chemistry in the London Institution. London: Kegan Paul, Trench, Trubner, and Co., Limited. 1901. Price 2s. 6d. Pp. 99.

have been promulgated respecting the most convenient test for the presence of arsenic in beer and such like compounds, that it is valuable to have a clear statement as to the exact character of the tests which have in ordinary work so long been relied on, but which in the special cases recently arisen seem to have been proved wanting. The original account of Marsh's method is here given, extending over some ten pages. Reinsch's test is also fully described, and its usefulness and limitations indicated. Unfortunately, Gutzeit's test is not described, although it has recently been shown to be particularly convenient and trustworthy. Particular attention is devoted to the testing of arsenic in special organo-metallic conditions when the ordinary tests fail, except such as involve destruction of organo-metallic compounds.

Professor Wanklyn advocates the employment of a red-heat, which, breaking up organo-metallic combinations, should always be employed where the formation of organo-metallic combinations is suspected. Full details are given of the author's method of dealing with suspected beer by his combustion method. The concluding chapter deals with "The Manchester Epidemic of Arsenical Poisoning, and the Lessons to be Learnt from It," and mainly consists in extracts from already published accounts, together with a strong condemnation of the method employed by Professor Delépine "to estimate approximately the quantity of the poison." The work is peculiarly timely, fairly comprehensive, based on wide and exceptional chemical experience, and interesting and attractive in style and general presentation. We heartily commend its consideration to all medical men and chemists having to deal with the still perplexing problems which arsenical contamination of food products have recently brought into such prominence.

#### LOCKWOOD'S APPENDICITIS. (a)

We have carefully read through the pages of this work and have derived a considerable amount of information on this important surgical subject. Whatever the reason is, appendicitis is a disease which appears to occur far more frequently nowadays than it did twenty years ago. At any rate, the affection is far more studied, and its conditions seem better understood and more quickly recognised, than it was in years gone by. The author enumerates the histories of eighty-three cases of appendicitis which came under his own personal observation, and as far as possible he has given the clinical history, morbid anatomy, and morbid histology of the cases in detail, and has then specifically commented on each individual case, as he states that it seems to him to be the only way by which to learn how to infer the morbid condition of the appendix from the clinical symptoms, and ultimately to place the treatment of appendicitis upon a scientific basis.

Mr. Lockwood divides his subject into twenty-one chapters and the work runs to 287 pp., including a very complete index. The last half-dozen chapters are very practical, and contain a vast amount of valuable information. We, therefore, strongly recommend this work to those operating surgeons particularly interested in appendicitis. The matter treated is well printed on good paper, and the book is neatly bound and reflects credit on the author and publishers alike.

#### A Surgical Oversight.

AN inquest was held a few days since at Bethnal Green on the body of a child, *et. 3*, who had sustained a wound of the cheek which was dressed at the North Eastern Hospital for Children. The wound became inflamed, and the child was certified to be suffering from erysipelas, but examination of the wound after death revealed the presence of a piece of wood which had not been detected when the wound was attended to. A verdict exonerating the medical officer from blame was returned.

(a) "Appendicitis, its Pathology and Surgery." By Charles Barrett Lockwood, F.R.C.S., Assistant Surgeon and Lecturer on Descriptive and Surgical Anatomy in St. Bartholomew's Hospital, &c. Pp. 287. Price 10s. net. Published by Macmillan and Co., London. 1901.

## Laboratory Notes.

### CHIVER'S CAMBRIDGE LEMONADE.

WE have submitted the Cambridge Lemonade which Messrs. Chivers and Son, Limited, are introducing this season to a critical chemical examination, and find it to consist of fine sugar crystals coated with the natural constituents of lemon juice, namely, the essential oil of lemons together with citric acid and a very small percentage of other organic acids usually found in lemons. We have verified the statement that it is free from any added acid. Lemonade prepared according to the directions given with each bottle affords a very refreshing and palatable summer beverage.

### ABREY'S EFFERVESCENT SALT.

ABREY'S Effervescent Salt is described as "an ideal laxative." On examination, we found it to be a skillfully granulated product, containing the usual saline constituents in due proportion. It has an agreeable acidulous taste, and, in doses of from one to two teaspoonfuls, procures an easy action of the bowels. Its palatableness will ensure its popularity with a large class of persons who object to nauseous salines, and are averse to drastic purgatives of vegetable origin.

### APOMORPHINE AND STRYCHNINE TABLOID.

MESSRS. BURROUGHS WELLCOME AND Co. have added to their list a tabloid containing apomorphine hydrochloride, gr.  $\frac{1}{16}$ , in association with strychnine hydrochloride, gr.  $\frac{1}{16}$ . This tabloid is intended for administration by the hypodermic method. The drawback hitherto attending the use of apomorphine, a drug possessed of useful therapeutical properties, has been the depression, sometimes very marked, which follows. Moreover, as it is not a very stable salt in solution, the latter requires to be freshly prepared. The association with strychnine effectively obviates the tendency to depression, and the tabloid form facilitates the preparation of a fresh, and therefore active solution. These tabloids are put up in tubes containing a dozen.

## Medical News.

### The Dublin Hospitals.

THE annual report of the Board of Superintendence of the Dublin hospitals has just been laid on the table of the House of Commons. It states that during the year ending March 31st., 1901, no culpable irregularity on the part of nurses or attendants was brought under the notice of the Board, nor had it any serious or well-founded complaint from the patients, while the members of the Board are gratified to speak with cordial approval of the work done in the Dublin hospitals. The opinion is advanced that the efficiency of these hospitals would be enhanced if more frequent visits were made by the Governors at irregular times. While the Board recognises that under existing circumstances it is not possible to exclude from hospital treatment patients who are not in a financial sense legitimate objects of charity, they feel that discrimination should be exercised to ensure that the funds provided for charitable relief should not be spent on persons who are competent to pay for such advantages. The Board are glad to observe that the medical staff of each hospital (with the exception of one) is now represented on the Governing Boards by some of its members. The Board again point out to the hospital authorities the importance of having properly qualified cooks to prepare invalid cooking for special cases. The report records a regret that in several hospitals scarcely sufficient care is bestowed on this subject, which is frequently even more important than the administration of medicine. The figures in the report show that on April 1st, 1900, there remained 921 patients in the hospitals which are under the supervision of the Board. The number admitted during the year was 11,601, making the whole number under treatment 12,522, of whom 11,611 left the wards either cured or relieved, or were discharged from other causes. The

deaths numbered 480. On March 31st last there were 911 patients under treatment. Exclusive of incurables the mortality was 3.93 per cent. on 11,118 cases, estimated on the numbers who were discharged, or who died, or whose cases had been treated to a termination. The total daily average number of beds occupied in the hospitals covered by this report was 946.05.

#### The Medico-Psychological Association.

The annual meeting commences on Thursday morning, July 25th, at Cork, and is at first occupied with the transaction of formal business. At 2 p.m. the annual meeting reassembles. The President for the ensuing year, Dr. Oscar T. Woods, will be introduced by the retiring President, Dr. Fletcher Beach, and the President deliver his Address, after which medals and prizes will be distributed. Following the President's Address papers will be read by John Carawell, L.R.C.P. Edin., L.F.P.S. Glasg. (Convener of Committee on Inebriates Corporation of Glasgow), "On the Working of the Inebriates Act"; Thomas Drapes, M.B., Medical Superintendent District Asylum, Ennisecorhy, Ireland, "Insanity and Phthisis"; J. Michael Nolan, L.R.C.P.I., M.P.C., Medical Superintendent District Asylum, Downpatrick, "Residual Lunatics and Recent Legislation"; F. W. Edridge-Green, M.D., F.R.C.S., Hatcheroff House, Hendon, London, N.W., "Evolution of the Colour Sense." E. D. O'Neill, L.R.C.P.I., Medical Superintendent the Asylum, Limerick, "The Superannuation Question—its Effect on Asylum Officials, with suggestions for further legislation on the subject." On Friday, July 26th, the meeting reassembles at 10 a.m., when the following papers will be read:—Professors Dixon and Bergin, "Stereoscopic Radiography." Joseph Shaw Bolton, M.D., B.S., B.Sc. Lond., Claybury Hall, Woodford Bridge, Essex, will give a lantern demonstration—"Gross Lesions of the Cerebrum"; George Revington, M.D., Univ. Dubl., M.P.C., Medical Superintendent Central Criminal Asylum, Dundrum, Ireland, will read a paper on "Mental Conditions Resulting in Homicide"; W. C. Sullivan, M.D., R.U.I., H.M. Prison, Pentonville, London, N., will read a paper entitled "Crime in General Paralytics"; 2 p.m.—John Keay, M.B., Medical Superintendent District Asylum, Inverness, will initiate a discussion—"On the Care of the Insane at Night"; A. R. Urquhart, M.D., F.R.C.P.E., Physician Superintendent James Murray's Royal Asylum, Perth, will read a paper on "Effect Upon Patients of Changes of Asylums"; Daniel F. Rambaut, M.D., Univ. Dubl., Assistant Medical Officer and Pathologist Richmond District Asylum, Dublin, will read a paper entitled "A Case of Cerebral Hemiatrophy"; R. E. Leeper, F.R.C.S.I., Resident Physician, St. Patrick's Hospital, Dublin, will read a paper entitled "Three Cases of Melancholia presenting Symptoms of Unusual Clinical Interest," and he will show microscopic specimens and photographs. The President, Dr. Oscar T. Woods, and Mrs. Oscar Woods will be "At Home" to members and their friends on Friday, July 26th, from four to seven o'clock, at the District Asylum, Cork. Saturday, July 27th, an excursion has been arranged to Killarney. The annual dinner will take place at the Imperial Hotel, Cork, on Thursday, July 25th, at 8 p.m.; tickets, £1 ls. each.

#### Fete of Messrs. Burroughs Wellcome and Co.

The annual gala of the employes of Messrs. Burroughs Wellcome and Co. took place on Saturday last, in the spacious grounds attached to the factory at Dartford. Athletic and aquatic sports were carried on from 11 o'clock in the morning until dark, when the grounds were illuminated. Luncheon was served to over 1,000 employes in a spacious marquee, which gives one an idea of the enormous growth of the drug trade and accessories connected with this firm. The present occasion was made additionally interesting by the presence of Mrs. Wellcome, daughter of Dr. Barnardo, of Surbiton, the newly-made bride of the principal, the toast of prosperity to the firm and happiness to the newly-wedded pair being proposed in felicitous terms by Mr. Passmore Edwards, and drunk with enthusiasm. Mrs. Wellcome subsequently presented the prizes at the conclusion of the sports, and during the day there was an exhibition

of relics and photographs from Omdurman and other parts of the Soudan, collected during the past winter by Mr. Wellcome, which attracted considerable attention.

#### Summer Trains de Luxe for the Holidays.

The International Sleeping Car Company issues its programme of trains *de luxe* services, composed of sleeping and restaurant cars only, for the present season. The Engadine Express runs daily *via* Calais to Sargans, Ragaz, and Coire, in connection with the 11.0 a.m. train from Victoria and Charing Cross. A section of this train runs through to Lucerne on Tuesdays, Wednesdays, Fridays, Saturdays, and Sundays. Another section runs through to Berne and Interlaken on Mondays and Thursdays. The Ostend-Swiss Express runs daily *via* Ostend to Bâle, and Lucerne in connection with the 10.0 a.m. train from Charing Cross and Victoria. The Carlsbad Express runs daily to Nuremberg, Eger, and Carlsbad, *via* Ostend, in connection with the 10.0 a.m. train from Charing Cross and Victoria. On Wednesdays and Saturdays only, passengers by this train may leave London by the 11.0 a.m. train, and travel *via* Calais.

#### Royal College of Surgeons, Ireland.

The following is a list of Scholarships and prizes awarded for the Summer Session, 1901:—Carmichael Scholarship, £15: W. E. Ormsby. Mayne Scholarship, £15: J. P. Byrne. Gold and Silver Medals in Operative Surgery: Gold Medal, C. W. Ewing; Silver Medal, A. Charles. Stoney Memorial Gold Medal in Anatomy: R. W. Burkitt. Practical Histology: A. N. Cawford, first prize, £3, and medal; J. S. Sheill, second prize, £1, and certificate. Practical Chemistry: E. J. Clarke, first prize, £3, and medal; J. M. Hayes, second prize, £1, and certificate; Public Health and Forensic Medicine: Miss J. C. Hargrave, first prize, £3, and medal; S. B. Hanbury, second prize, £1, and certificate. *Materia Medica*: J. S. Sheill, first prize, £3, and medal; J. M'Quillan, second prize, £1, and certificate. Practical Pharmacy: Miss C. O'Meara, first prize, £3, and medal; J. M. Aloor, second prize, £1, and certificate. Biology: R. Bury, first prize, £3, and medal; F. X. Costello, second prize, £1, and certificate. The Schools of Surgery will resume work after the summer recess on Tuesday, October 1st.

#### The New Physiological Laboratory for Edinburgh.

On Saturday last the new physiological laboratory which has been built by Mrs. Cox in memory of her father, the late Professor John Hughes Bennett, M.D., F.R.S., was formally handed over to the University in the presence of a brilliant academic gathering. Sir William Muir, the Principal, presided, and among the members of the University and others who were present were Sir J. Burdon Sanderson, Sir J. Batty Tuke, M.P., Sir James Crichton Browne, Sir William Turner, Sir William Gairdner, Sir Henry Littlejohn, Sir Ludovic Grant, Professors Chiene, Simpson, Stockman, Schafer, Boyce, &c. Apologies for absence were received, among others, from Lord Lister and Sir Michael Foster. The laboratory is designed for the teaching of experimental physiology, and consists of two rooms—one fitted with all the apparatus necessary for practical work by individual students, the other a small theatre where the lecturers may give demonstrations to a class. After the opening ceremony, Sir J. Burdon Sanderson delivered an address on the life and work of Dr. Hughes Bennett.

#### Vital Statistics.

The deaths registered in the week ending July 13th, in 36 large towns of Great Britain and Ireland corresponded to an annual rate of 15.6 per 1,000 of their aggregate population, which is estimated at 11,463,026 persons in the middle of this year:—

Birkenhead 26, Birmingham 17, Blackburn 12, Bolton 17, Bradford 15, Brighton 13, Bristol 10, Burnley 15, Cardiff 12, Croydon 10, Derby 10, Dublin 21, Edinburgh 15, Glasgow 17, Gateshead 18, Halifax 9, Huddersfield 15, Hull 11, Leeds 18, Leicester 10, Liverpool 25, London 14, Manchester 17, Newcastle-on-Tyne 19, Norwich 13, Nottingham 15, Oldham 13, Plymouth 10, Portsmouth 20, Preston 21, Salford 19, Sheffield 14, Sunderland 18, Swansea 16, West Ham 14, Wolverhampton 13. The

highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 2·3 in Birkenhead; from whooping-cough, 1·1 in Swansea and 1·3 in Bradford; and from diarrhoeal diseases, 2·2 in Portsmouth and in Leeds, 2·3 in Preston, 2·9 in Sheffield, 6·0 in Liverpool, and 6·6 in Birkenhead. In none of the large towns did the death-rate from scarlet fever or from "fever" reach 1·0 per 1,000. The 66 deaths from diphtheria included 24 in London, 6 in Liverpool, 5 in Manchester, 4 in Leicester, 4 in Leeds, 3 each in West Ham, Cardiff, Salford, and Sheffield. One death from small-pox was registered in Liverpool, one in Glasgow, but not one in any other of the large towns.

**Lotus Arabeticus.**

TRADITIONALLY the lotus has a sinister reputation; and in practice the military and civil authorities in Egypt have found that it is highly poisonous in certain stages of its growth to the horses, sheep, and goats for whom it has been used as fodder. Some time back investigations were undertaken by Mr. Wyndham Dunstan, F.R.S., and Mr. T. R. Henry to discover the poisonous element in the Egyptian lotus—*Lotus Arabeticus*, and they found that its poisonous constituents included prussic acid. The poisonous property of the lotus appears to be due to the action of an enzyme, lotase, on a glucoside, lotusin, which breaks up into prussic acid and other constituents. The amount of prussic acid given by the plant differs according to the stage of its growth. The formation of the poison seems to reach its maximum at about the seeding period, and after that to diminish rapidly. The Arabs are aware that the plant itself is safe to use as a fodder when the seeds are quite ripe, but not before. During the ripening of the seeds the lotusin which contains the prussic acid disappears.

**Friedenheim Hospital.**

AN influentially signed appeal has been issued on behalf of the "Home for the Dying" at Swiss Cottage, the present financial position whereof is very precarious. Additional accommodation for the nursing staff is urgently required, and the building itself is in great need of repairs.

THE Society for the Study of Disease in Children has recently held a most successful provincial meeting at Liverpool. Although the association is still in its infancy, no less than seventy-three members attended the gathering. The programme included a number of papers on practical subjects connected with pediatrics, some of them being of a conspicuously advanced and scientific nature. There was the usual dinner, held in this case at the Adelphi Hotel, under the presidency of Dr. Ernest Sansom. Several excursions were organised and it may safely be said that the problem of how to get over the most ground within a limited time could hardly have been more conclusively answered. The Honorary Secretary of this most energetic society is Mr. Sydney Stephenson, who will be pleased to furnish any required information as to its scope and organisation. The next provincial meeting is to take place at Manchester in June, 1902.

**"Jelly a la Lemco."**

If our readers want an excellent and very nourishing jelly we should recommend the following:—Put into a stewpan one quart of cold water or veal stock, the rind of half a lemon, four cloves, a dessertspoonful of salt, half a teaspoonful of peppercorns, a dessertspoonful of tarragon vinegar, a small onion, a sprig of parsley, 2 ozs. of leaf gelatine and the well-beaten whites and shells of three eggs. Let all this come to the boil, the scum rising to the top, then draw aside the pan and cover it for five minutes. Pour a little boiling water through a jelly bag and then strain the jelly through it and add a teaspoonful of Lemco.

**Glasgow University Medical Passes.**

THE following have passed the fourth (final) professional examination in medicine at Glasgow University: For M.B., C.M.—Duncan Davie, William Henry Ferran, Shushil Kumar Roy, John Poynter Small, David Wallace Smith.

For M.B., Ch.B.—Martha Adams, John Anderson.

Thomas Anderson, William Archibald, James O. Barclay, John S. Barr, William H. Brown, William M. Brown, George Frederick Buchan, Ernest C. Burnett, Patrick T. Cairns, Samuel J. Cameron, Robert D. Campbell, James B. W. Cook, Ernest H. Cramb, Andrew Currie, David B. Davidson, James Davidson, M.A., G. H. G. Davie, Alexander Doig, Reginald N. Dunlop, George B. Eadie, William Elder, William W. Farrar, John Forrest, John A. Garden, Andrew P. Granger, John Gregor, George P. Harlane, Francis J. Henry, Douglas W. Hunter, Matthew Hunter, William J. Isbister, Thomas H. Jack, Daniel E. Kilpatrick, David Kyle, M.A., John Lambie, F. J. Lochrane, James W. M'Dougall, Thomas M'Learen, Hugh A. M'Lean, George W. M'Millan, James M'Pherson, M.A., Edward Magoveny, Jacob Mains, James G. Miller, Robert H. Mills, William A. Milne, Samuel J. Moore, Alan H. Muir, Robert Paterson, John Paton, James K. Patrick, Robert Ramsay, Peter M. Reid, William Robertson (Kilmarnock), Thomas R. Rodger, Charles J. Ross, B.A., David Shannon, Donald Steel, John Strathearn, Alexander D. Thompson, James Nathaniel Todd, Joseph G. Tankinson, John W. Turner, Robert W. Valentine, Albert E. Wainwright, James Walker, George S. Wallace, Peter M. Waugh, W. W. W. Wilson, Martha Adams, Mabel Hardie, Alice Moorhouse, Mary J. Pirret, Agnes B. Sloan, Elizabeth M. Sloan.

The following attained distinction. S. indicates surgery and clinical surgery; P. practice of medicine and clinical medicine; M. midwifery:—

John Anderson (P), William Archibald (P), Robert Wellwood Auld (P), James Oastler Barclay (P), John Stoddart Barr (P), William Herbert Brown (P), William Macalister Brown (P), George Frederick Buchan (P) Samuel James Cameron (PM), Edward Seymour Chapman (P), David Beattie Davidson (P), James Davidson, M.A. (PM), Reginald Nairn Dunlop (M), Janet Bissland Higgins (P), Douglas William Hunter (P), David Kyle M.A. (SP), James M'Pherson, M.A. (P), Edward Magoveny (SP), Jacob Mains (P), William Alexander Milne (P), Alice Moorhouse (P), Alan Howie Muir (P), Robert Ramsey (M), Peter Mackenzie Reid (P), William Robertson, Kilmarnock (P), Agnes Benkier Sloan (P), Donald Steel (S), Alexander Dey Thompson (SPM), Joseph Goodwin Tomkinson (P), Robert Warden Valentine (M), Albert Ernest Wainwright (P), James Walker (PM).

**Society of Apothecaries of London, July, 1901.**

THE following candidates have passed:—Surgery.—C. H. Allan, Sections I. and II.; A. G. H. Anthonisz; Section I.; F. A. Beattie, Sections I. and II.; P. C. Burgees, Section I.; C. E. C. Child, Section I.; T. J. M. Clapperton, Sections I. and II.; E. A. Dunn, Section II.; J. P. E. Henery; H. C. Hocken, Section II.; C. E. A. Huddart, Sections I. and II.; R. L. Jones, Sections I. and II.; F. P. Joscelyne, Section II.; C. C. Morgan, Section I.; B. E. Sansom, Section II.; C. V. Smith; P. P. Tobit, Section I.; F. I. Trimmer, Sections I. and II.; A. G. Wilson, Sections I. and II.; E. Yoxall, Section I.

Medicine.—F. A. Beattie, Sections I. and II.; J. E. Bolton, Section I.; G. M. Crockett, Section I.; K. A. Dawson, Section I.; E. A. Dunn, Section II.; H. C. Hocken, Sections I. and II.; F. P. Joscelyne, Section II.; A. E. Malaher; M. E. Martin, Section I.; E. S. Perkins; H. Richardson, Sections I. and II.; P. G. Sheppard, Sections I. and II.; J. E. Skey, Section I.; A. G. Wilson, Sections I. and II.

Forensic Medicine.—F. A. Beattie, J. E. Bolton, G. M. Crockett, K. A. Dawson, E. H. Forjett, C. J. Francis, H. C. Hocken, M. E. Martin, E. S. Perkins, F. P. Rose, J. E. Skey, and A. G. Wilson.

Midwifery.—F. A. Beattie, F. G. Bennett, F. J. Birks, P. J. R. Bucknill, W. V. Braddon, A. N. Collier, W. H. Crossley, W. R. Davies, C. W. Gibson, J. M. King, E. A. Le Maistre, D. E. Lockwood, M. B. Oliver, J. A. W. Webster, A. G. Wilson.

The L.S.A. diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery.—F. A. Beattie, F. J. Birks, P. J. R. Bucknill, E. A. Dunn, H. C. Hocken, F. P. Joscelyne, A. E. Malaher, C. V. Smith, and A. G. Wilson.

### TRAINED MEN FOR THE ARMY MEDICAL CORPS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following official information has been sent us for publication:—"Trained men are required for the Royal Army Medical Corps for one year's service or the duration of the war. Full particulars can be obtained from the Chief Recruiting Staff Officer, St. George's Barracks, London, W.C."

G. F. DAVIDSON, Colonel.  
Chief Recruiting Staff Officer.

St. George's Barracks, London, W.C.,  
July 22nd, 1901.

Mrs. S. G. M.—You had better apply to a local medical man who may be willing to impart the necessary instruction in return for your daughter's services. It would, however, be better for her to prepare for the "minor" qualification of the Pharmaceutical Society, information respecting which can be obtained at the Offices, Bloomsbury Square, W.C.

X. V.—We shall be pleased to publish the case if you will forward us the details. It ought not to be difficult to veil the identity of the patient sufficiently to set all qualms at rest.

N. Y.—The subject of your article is well worthy of consideration, but the data upon which your sweeping strictures are based do not appear to us to warrant so much declamation. The matter is of purely scientific interest, and should be approached in a scientific spirit, leaving individuals out of the question. We are unable to make use of it as it stands.

Dr. M.—Such visits are purely a matter of courtesy, and you have no right to feel aggrieved if they are not made. It is highly undesirable to make every little social omission a pretext for cultivating ill-will both in your interest and in that of the newcomer.

Dr. POUJET.—We have no knowledge of the anti-tuberculous treatment in question. There are many "on the market," all equally untrustworthy. You would hardly be justified in experimenting with a "serum" until you had taken steps to ascertain its precise nature and effects, and this you should proceed to do. Your patient's wish does not exonerate you from all responsibility, as you seem to imagine.

## Diary for the Week.

### ENGLAND.

Daily this week, the Congress on Tuberculosis at the Queen's Hall, London.

FRIDAY, JULY 26TH.

SOCIETY FOR THE STUDY OF DISEASES IN CHILDREN.—Annual meeting at 11 Chandos St., London, W., 5.30 p.m.: Presentation of Report and Election of Officers.

TUESDAY, JULY 30TH TO FRIDAY, AUGUST 2ND.

BRITISH MEDICAL ASSOCIATION Annual meeting to be held this year at Cheltenham. First general meeting Tuesday, at 2.30 p.m. Sectional and general meetings daily. On Saturday, excursion to Wye Valley.

### IRELAND.

THURSDAY, JULY 25TH, AND FRIDAY, JULY 26TH.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—Annual meeting to be held this year at Cork. Hours of meeting, 10 a.m. and 2 p.m.

MONDAY, JULY 29TH, TUESDAY, JULY 30TH, WEDNESDAY, JULY 31ST.

BRITISH PHARMACEUTICAL CONFERENCE, to be held this year in Dublin. Sessions of Conference in Lecture Theatre, Royal Dublin Society, 10 a.m. to 1 p.m. and 2 p.m. to 4 p.m. each day.

## Appointments.

CARGILL, L. VERNON, F.R.C.S.Eng., L.R.C.P.Lond., L.S.A., Surgeon to the Royal Eye Hospital, Southwark.  
DUNLEA, M. P., M.D., B.U.I., Certifying Surgeon for the Riverstown District in the County of Cork.  
FAGAN, P. J., L.R.C.P.Irel., Lecturer on Elementary Physics in the Catholic University Medical School, Dublin.  
HAMILTON, W. M., M.D., R.U.I., Medical Officer of Health of Eccles Municipal Borough.  
HAYES, W. B., M.D., R.U.I., Certifying Surgeon for the Union of Tralee, in the County of Kerry.  
HOGG, J. A., M.B.C.S.Eng., L.R.C.P.Lond., Medical Officer of Health of Shardlow Rural Sanitary District.  
MASON, J. J., L.R.C.P.Édin., L.R.C.S.Édin., Medical Officer of Health of Bollington Urban Sanitary District.  
MADDEVER, J. C., M.D.Glasg., Certifying Surgeon for the Brownhills and Aldridge District of Staffordshire.

McCLIMARY, G. F., M.B.Camb., L.S.A., Medical Officer of Health of Battersea Metropolitan Borough.  
MEACHEN, G. NORMAN, M.B., B.S.Lond., M.R.C.P.Édin., M.B.C.S., Clinical Assistant to the Hospital for Diseases of the Skin, Blackfriars.  
MILLARD, C. K., M.D.Édin., Medical Officer of Health of Leicester County Borough.  
MUIRHEAD, JAMES, M.B., B.S.Durb., Senior House Physician to the Royal Infirmary, Newcastle-on-Tyne.  
O'BRIEN, D. J., L.R.C.P., L.R.C.S., Certifying Surgeon for the Darrow Dispensary District, Queen's County.  
PRITCHARD, W. G., L.B.C.P., L.R.C.S., Certifying Surgeon for the Bethesda District of the County of Carnarvon.  
ROUTH AMAND, M.D., B.S., F.R.C.P.Lond., Consulting Physician to the Samaritan Free Hospital for Women, London.  
TREDNICK, A. S., L.R.C.P.Lond., M.B.C.S.Eng., Certifying Surgeon for the Melbourne District of Derbyshire.

## Vacancies.

Blackpool Corporation.—Medical Officer of Health for the Borough. Salary £400, rising to £500 per annum. Age not to exceed 50 years. Candidates must devote his whole time to the duties. Forms of application to be obtained from the Town Clerk. (See Advt.)  
Cumberland and Westmorland Asylum, Garlands, Carlisle.—Senior Assistant Medical Officer, unmarried. Salary £150 a year, rising to £180, with board, lodging, &c.  
Devon County Asylum, Exminster, near Exeter.—Third Assistant Medical Officer. Salary £125, rising to £150, with board, lodging, &c. Applications to the Medical Superintendent.  
Halifax Union Hospital, Salterhebble.—Resident Medical Officer. Salary £140 per annum, with apartments, rations, and washing.  
Hospital for Sick Children, Newcastle-on-Tyne.—Resident Medical Officer. Salary £100, with board, lodgings, and laundry.  
London Hospital, Whitechapel, E.—Assistant Director of the Pathological Institute. Salary £200 per annum.  
North Wales Counties Lunatic Asylum, Denbigh.—Second Assistant Medical Officer. £120 per annum, increasing to £160, with board, residence, and washing.  
Nottingham General Dispensary.—Two Assistant Resident Surgeons, unmarried. Salaries £160 per annum each, increasing by £10 every year, with furnished apartments, attendance, light, and fuel.  
Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board (excluding stimulants) and apartments.  
Rural District Council of Bishop Auckland.—Medical Officer of Health for the Rural District. Salary £350 per annum. Whole time to be devoted to the office. Applications to the Clerk of the Council, Bishop Auckland.  
St. Matthew, Bethnal Green Infirmary, Cambridge Road, N.E.—First Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and laundry.  
University of Sydney, New South Wales.—Professor of Pathology. Salary £900 per annum. Pension £400 per annum after twenty years' service. £100 allowed for passage. Further particulars of the Agent-General for New South Wales, 9, Victoria Street, London, S.W.  
Wolverhampton and Staffordshire General Hospital.—Assistant House Physician for six months. Honorarium at rate of £75 per annum, with board, lodging, and washing. Also Assistant House Surgeon for six months; same honorarium.

## Births.

BENNETT.—On July 19th, at 33 Vancouver Road, Forest Hill, S.E., the wife of Colin E. Bennett, L.R.C.P., M.B.C.S.Eng., of a son.  
MERRY.—On July 21st, at 2 Chiswick Place, Eastbourne, the wife of W. J. C. Merry, M.D., of a son.  
SKINNER.—On July 17th, at Bank House, Rye, Sussex, the wife of Ernest W. Skinner, M.D., of a daughter.  
WHITE.—On July 16th, at the Dover House, Bigbrooke, Northamptonshire, the wife of Percy Stanhope White, M.B.C.S., L.R.C.P.Lond., of a daughter.

## Marriages.

GERVIS.—Old.—On July 18th, at St. Augustine's Church, Kilburn Arthur Frederick Gervis, M.B.C.S., L.R.C.P., of No. 1 Steele's Road, Hampstead, son of Frederick H. Gervis, M.B.C.S., to Ethel, eldest daughter of Charles Old, of Brondesbury.  
MISKIN.—MISKIN.—On July 20th, at the Parish Church, Eltham, Kent, Ernest Miskin, M.B., M.B.C.S., L.R.C.P., son of Dr. Miskin, of Slade House, Kennington, to Mabel Caroline, only daughter of W. P. Miskin, Eltham, Kent.

## Deaths.

BEGG.—At Hout Kop, near Vereeniging, on July 11th, Charles Begg, aged 21, killed in action, eldest son of Charles Begg, M.B., C.M.Édin., of Bath.  
MIDDLETON.—On July 20th, at the Royal Infirmary, Preston, Basil Charles Middleton, M.B., Ch.B., eldest son of Charles E. Middleton, Adlington, Lancs., aged 25 years.  
NEALE.—On July 16th, at London Road, Leicester, John Headley Neale, M.B.Édin., M.B.C.P.Lond., aged 51 years.  
PEARSE.—On July 19th, at the Bookery, Blofield, Arthur Pearse, M.D.—formerly of Botesdale, Suffolk, aged 64 years.  
BIGGS.—On July 12th, John Arthur Biggs, M.B.C.S.Eng., L.R.C.P.Lond., L.S.A., of Henley-on-Thames.

THE

### COMBATING OF TUBERCULOSIS IN THE LIGHT OF THE EXPERI- ENCE THAT HAS BEEN GAINED IN THE SUCCESSFUL COMBATING OF OTHER INFECTIOUS DISEASES. (a)

By Geh. Med.-Rath Professor Dr. ROBERT KOCH,  
Direktor des Instituts für Infektionskrankheiten in Berlin.

We understand by tuberculosis only those morbid conditions which are caused by the tubercle bacillus. In by far the majority of cases of tuberculosis the disease has its seat in the lungs, and has also begun there. From this fact it is justly concluded that the germs of the disease, *i.e.*, the tubercle-bacilli, must have got into the lungs by inhalation. As to the question where the inhaled tubercle-bacilli come from there is also no doubt. On the contrary, we know with certainty that they get into the air with the sputum of consumptive patients. This sputum, especially in advanced stages of the disease, almost always contains tubercle bacilli, sometimes in incredible quantities. By coughing, and even speaking, it is flung into the air in little drops, *i.e.*, in a moist condition, and can at once infect persons who happen to be near the coughers. But then it may also be pulverised when dried, in the linen or on the floor for instance, and get into the air in the form of dust.

In this manner a complete circle, a so-called *circulus vitiosus*, has been formed for the process of infection, from the diseased lung, which produces phlegm and pus containing tubercle-bacilli, to the formation of moist and dry particles (which, in virtue of their smallness, can keep floating a good while in the air), and finally to new infection, if particles penetrate with the air into a healthy lung and originate the disease anew. But the tubercle-bacilli may get to other organs of the body in the same way, and thus originate other forms of tuberculosis. This, however, is a considerably rarer case. The sputum of consumptive people, then, is to be regarded as the main source of the infection of tuberculosis. On this point, I suppose, all are agreed. The question now arises whether there are not other sources too, copious enough to demand consideration in the combating of tuberculosis.

Great importance used to be attached to the hereditary transmission of tuberculosis. Now, however, it has been demonstrated by thorough investigation that, though hereditary tuberculosis is not absolutely non-existent, it is nevertheless extremely rare, and we are at liberty, in considering our prac-

tical measures, to leave this form of origination entirely out of account.

But another possibility of tuberculous infection exists, as is generally assumed, in the transmission of the germs of the disease from tuberculous animals to man. This manner of infection is generally regarded nowadays as proved, and as so frequent that it is even looked upon by not a few as the most important, and the most rigorous measures are demanded against it. In this Congress also the discussion of the danger with which the tuberculosis of animals threatens man will play an important part. Now, as my investigations have led me to form an opinion deviating from that which is generally accepted, I beg your permission, in consideration of the great importance of this question, to discuss it a little more thoroughly.

Genuine tuberculosis has hitherto been observed in almost all domestic animals, and most frequently in poultry and cattle. The tuberculosis of poultry, however, differs so much from human tuberculosis that we may leave it out of account as a possible source of infection for man. So, strictly speaking, the only kind of animal tuberculosis remaining to be considered is the tuberculosis of cattle, which, if really transferable to man, would indeed have frequent opportunities of infecting human beings through the drinking of the milk and the eating of the flesh of diseased animals.

Even in my first circumstantial publication on the etiology of tuberculosis I expressed myself regarding the identity of human tuberculosis and bovine tuberculosis with reserve. Proved facts which would have enabled me sharply to distinguish these two forms of the disease were not then at my disposal, but sure proof of their absolute identity were equally undiscoverable, and I therefore had to leave this question undecided. In order to decide it, I have repeatedly resumed the investigations relating to it, but so long as I experimented on small animals, such as rabbits and guinea pigs, I failed to arrive at any satisfactory result, though indications which rendered the difference of the two forms of tuberculosis probable were not wanting. Not till the complaisance of the Ministry of Agriculture enabled me to experiment on cattle, the only animals really suitable for these investigations, did I arrive at absolutely conclusive results. Of the experiments which I have carried out during the last two years along with Professor Shütz, of the Veterinary College in Berlin, I will tell you briefly some of the most important.

A number of young cattle which had stood the tuberculin test, and might therefore be regarded as free from tuberculosis, were infected in various ways with pure cultures of tubercle-bacilli taken from cases of human tuberculosis; some of them got the tuberculous sputum of consumptive patients direct. In some cases the tubercle-bacilli or the sputum were injected under the skin, in others into the peritoneal cavity, in others into the jugular vein.

(a) Abstract of Address read before the British Congress on Tuberculosis, London, July, 1901.

Six animals were fed with tuberculous sputum almost daily for seven or eight months; four repeatedly inhaled great quantities of bacilli, which were distributed in water and scattered with it in the form of spray. None of these cattle (there were nineteen of them) showed any symptoms of disease, and they gained considerably in weight. From six to eight months after the beginning of the experiments they were killed. In their internal organs not a trace of tuberculosis was found. Only at the places where the injections had been made small suppurative foci had formed, in which few tubercle-bacilli could be found. This is exactly what one finds when one injects dead tubercle-bacilli under the skin of animals liable to contagion. So the animals we experimented on were affected by the living bacilli of human tuberculosis exactly as they would have been by dead ones; they were absolutely insusceptible to them.

The result was utterly different, however, when the same experiment was made on cattle free from tuberculosis with tubercle-bacilli that came from the lungs of an animal suffering from bovine tuberculosis. After an incubation-period of about a week the severest tuberculous disorders of the internal organs broke out in all the infected animals. It was all one whether the infecting matter had been injected only under the skin or into the peritoneal cavity or the vascular system. High fever set in, and the animals became weak and lean; some of them died after a month and a half to two months, others were killed in a miserably sick condition after three months. After death extensive tuberculous infiltrations were found at the place where the injections had been made, and in the neighbouring lymphatic glands, and also far advanced alterations of the internal organs, especially the lungs and the spleen. In the case in which the injection had been made into the peritoneal cavity the tuberculous growths which are so characteristic of bovine tuberculosis were found on the omentum and peritoneum. In short, the cattle proved just as susceptible to infection by the bacillus of bovine tuberculosis as they had proved insusceptible to infection by the bacillus of human tuberculosis. I wish only to add that preparations of the organs of the cattle which were artificially infected with bovine tuberculosis in these experiments are exhibited in the Museum of Pathology and Bacteriology.

An almost equally striking distinction between human and bovine tuberculosis was brought to light by a feeding experiment with swine. Six young swine were fed daily for three months with the tuberculous sputum of consumptive patients. Six other swine received bacilli of bovine tuberculosis with their food daily for the same period. The animals that were fed with sputum remained healthy and grew lustily, whereas those that were fed with the bacilli of bovine tuberculosis soon became sickly, were stunted in their growth, and half of them died. After three months and a half the surviving swine were all killed and examined. Among the animals that had been fed with sputum no trace of tuberculosis was found, except here and there little nodules in the lymphatic glands of the neck, and in one case a few grey nodules in the lungs. The animals, on the other hand, which had eaten bacilli of bovine tuberculosis had, without exception (just as in the cattle experiment), severe tuberculous diseases, especially tuberculous infiltration of the greatly enlarged lymphatic glands of the neck and of the mesenteric glands, and also extensive tuberculosis of the lungs and the spleen.

The difference between human and bovine tuberculosis appeared not less strikingly in a similar experiment with asses, sheep, and goats, into whose vascular systems the two kinds of tubercle-bacilli were injected.

Our experiments, I must add, are the only ones that have led to this result. If one studies the older literature of the subject, and collates the reports of the numerous experiments that were made in former times by Chauveau, Günther and Harms, Bollinger, and others, who fed calves, swine, and goats with tuberculous material, one finds that the animals that were fed with the milk and pieces of the lungs of tuberculous cattle always fell ill of tuberculosis, whereas those that received human material with their food did not. Comparative investigations regarding human and bovine tuberculosis have been made very recently in North America by Smith, Dinwiddie and Frothingham, and their result agreed with that of ours. The unambiguous and absolutely conclusive result of our experiments is due to the fact that we chose methods of infection which exclude all sources of error, and carefully avoided everything connected with the stalling, feeding, and tending of the animals that might have a disturbing effect on the experiments.

Considering all these facts, I feel justified in maintaining that human tuberculosis differs from bovine, and cannot be transmitted to cattle. It seems to me very desirable, however, that these experiments should be repeated elsewhere in order that all doubt as to the correctness of my assertion may be removed.

But now, how is it with the susceptibility of man to bovine tuberculosis? This question is far more important to us than that of the susceptibility of cattle to human tuberculosis, highly important as that is too. It is impossible to give this question a direct answer, because, of course, the experimental investigation of it with human beings is out of the question. Indirectly, however, we can try to approach it. It is well known that the milk and butter consumed in great cities very often contain large quantities of the bacilli of bovine tuberculosis in a living condition, as the numerous infection-experiments with such dairy products on animals have proved. Most of the inhabitants of such cities daily consume such living and perfectly virulent bacilli of bovine tuberculosis, and unintentionally carry out the experiment which we are not at liberty to make. If the bacilli of bovine tuberculosis were able to infect human beings, many cases of tuberculosis caused by the consumption of aliments containing tubercle-bacilli could not but occur among the inhabitants of great cities, especially the children. And most medical men believe that this is actually the case.

In reality, however, it is not so. That a case of tuberculosis has been caused by aliments can be assumed with certainty only when the intestine suffers first—i.e., when a so-called primary tuberculosis of the intestine is found. But such cases are extremely rare. Among many cases of tuberculosis examined after death, I myself remember having seen primary tuberculosis of the intestine only twice. Among the great post-mortem material of the Charité Hospital in Berlin ten cases of primary tuberculosis of the intestine occurred in five years. Among 933 cases of tuberculosis in children at the Emperor and Empress Frederick's Hospital for Children, Baginsky never found tuberculosis of the intestine without simultaneous disease of the lungs and the bronchial glands. Among 3,104 post-mortems of tuberculous children, Biedert observed only sixteen cases of primary tuberculosis of the intestine. I could cite from the literature of the subject many more statistics of the same kind, all indubitably showing that primary tuberculosis of the intestine, especially among children, is a comparatively rare disease, and of these few cases that have been enumerated, it is by no means certain that they were due to infection by bovine tuberculosis. It is just as likely that they were caused by the widely propagated bacilli of human tuberculosis, which may

have got into the digestive canal in some way or other—for instance, by swallowing saliva of the mouth. Hitherto nobody could decide with certainty in such a case whether the tuberculosis of the intestine was of human or of animal origin. Now we can diagnose them. All that is necessary is to cultivate in pure culture the tubercle-bacilli found in the tuberculous material, and to ascertain whether they belong to bovine tuberculosis by inoculating cattle with them. For this purpose I recommend subcutaneous injection, which yields quite specially characteristic and convincing results. For half a year past I have occupied myself with such investigations, but, owing to the rareness of the disease in question, the number of the cases I have been able to investigate is but small. What has hitherto resulted from this investigation does not speak for the assumption that bovine tuberculosis occurs in man.

Though the important question whether man is susceptible to bovine tuberculosis at all is not yet absolutely decided, and will not admit of absolute decision to-day or to-morrow, one is nevertheless already at liberty to say that, if such a susceptibility really exists, the infection of human beings is but a very rare occurrence. I should estimate the extent of infection by the milk and flesh of tuberculous cattle, and the butter made of their milk, as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it.

So the only main source of the infection of tuberculosis is the sputum of consumptive patients, and the measures for the combating of tuberculosis must aim at the prevention of the dangers arising from its diffusion. Well, what is to be done in this direction? Several ways are open. One's first thought might be to consign all persons suffering from tuberculosis of the lungs, whose sputum contains tubercle-bacilli to suitable establishments. This, however, is not only absolutely impracticable, but also unnecessary. For a consumptive who coughs out tubercle-bacilli is not necessarily a source of infection on that account, so long as he takes care that his sputum is properly removed and rendered innocuous. This is certainly true of very many patients, especially in the first stages, and also of those who belong to the well-to-do classes, and are able to procure the necessary nursing. But how is it with people of very small means? Every medical man who has often entered the dwellings of the poor, and I can speak on this point from my own experience, knows how sad is the lot of consumptives and their families there. The whole family have to live in one or two small, ill-ventilated rooms. The patient is left without the nursing he needs, because the able-bodied members of the family must go to their work. How can the necessary cleanliness be secured under such circumstances? How is such a helpless patient to remove his sputum, so that it may do no harm? But let us go a step further and picture the condition of a consumptive patient's dwelling at night. The whole family sleep crowded together in one small room. However cautious he may be, the sufferer scatters the morbid matter secreted by his diseased lungs every time he coughs, and his relatives close beside him must inhale this poison. Thus whole families are infected. They die out, and awaken in the minds of those who do not know the infectiousness of tuberculosis the opinion that it is hereditary, whereas its transmission in the cases in question was due solely to the simplest processes of infection, which do not strike people so much, because the consequences do not appear at once, but generally only after the lapse of years. Often, under such circumstances, the infection is not restricted to a single family, but spreads in densely inhabited tenement-

houses to the neighbours, and then, as the admirable investigations of Biggs have shown in the case of the densely peopled parts of New York, regular nests or foci of disease are formed.

If we are not able at present to get rid of the danger which small and overcrowded dwellings involve, all we can do is to remove the patients from them, and, in their own interests and that of the people about them, to lodge them better; and this can be done only in suitable hospitals. But the thought of attaining this end by compulsion of any kind is very far from me; what I want is that the consumptives may be enabled to obtain the nursing they need better than they can obtain it now. At present a consumptive in an advanced stage of the disease is regarded as incurable and as an unsuitable inmate for a hospital. The consequence is that he is reluctantly admitted and dismissed as soon as possible. The patient too, when the treatment seems to him to produce no improvement, and the expenses, owing to the long duration of his illness, weigh heavily upon him, is himself animated by the wish to leave the hospital soon. That would be altogether altered if we had special hospitals for consumptives, and if the patients were taken care of there for nothing, or at least at a very moderate rate. To such hospitals they would willingly go; they could be better treated and cared for there than is now the case. As however, unfortunately, the aid of the state, the municipalities, and rich benefactors will probably not be forthcoming for a long time yet, we must for the present resort to other measures that may pave the way for the main measures just referred to, and serve as a supplement and temporary substitute for it.

Among such measures I regard obligatory notification as specially valuable. In the combating of all infectious diseases it has proved indispensable as a means of obtaining certain knowledge as to their state, especially their dissemination, their increase and decrease. In the conflict with tuberculosis also we cannot dispense with obligatory notification; we need it not only in order to inform ourselves as to the dissemination of this disease, but mainly in order to learn where help and instruction can be given, and especially where the disinfection which is so urgently necessary when consumptives die or change their residences has to be effected. Fortunately it is not at all necessary to notify all cases of tuberculosis, nor even all cases of consumption, but only those that, owing to the domestic conditions, are sources of danger to the people about them.

There is another measure, closely connected with notification, viz., disinfection, which, as already mentioned, must be effected when consumptives die or change their residence, in order that those who next occupy the infected dwelling may be protected against infection. Moreover, not only the dwellings but also the infected beds and clothes of consumptives ought to be disinfected. A further measure, already recognised on all hands as effective, is the instructing of all classes of the people as to the infectiousness of tuberculosis, and as to the best way of protecting oneself. The fact that tuberculosis has considerably diminished in almost all civilised states of life is attributable solely to the circumstance that knowledge of the contagious character of tuberculosis has been more and more widely disseminated, and that caution in intercourse with consumptives has increased more and more in consequence. Another measure, which has come into the foreground of late, and which at this moment plays to a certain extent a paramount part in all efforts for the combating of tuberculosis, works in quite another direction. I mean the founding of sanatoria for consumptives.

That tuberculosis is curable in its early stages

must be regarded as an undisputed fact. The idea of curing as many tuberculous patients as possible in order to reduce the number of those that reach the infectious stage of consumption, and thus to reduce the number of fresh cases, was therefore a very natural one. The only question is whether the number of persons cured in this way will be great enough to exercise an appreciable influence on the retrogression of tuberculosis. I will try to answer this question in the light of the figures at my disposal.

If now, in conclusion, we glance back once more to what has been done hitherto for the combating of tuberculosis, and forward to what has still to be done, we are at liberty to declare with a certain satisfaction that very promising beginnings have already been made. Among these I reckon the consumption hospitals of England, the legal regulations regarding notification in Norway and Saxony, the organisation created by Biggs in New York, the sanatoria, and the instruction of the people. All that is necessary is to go on developing these beginnings, to test, and if possible to increase their influence on the diminution of tuberculosis, and wherever nothing has yet been done, to do likewise.

If we are continually guided in this enterprise by the spirit of genuine preventive medical science, if we utilise the experience gained in conflict with other pestilences, and aim, with clear recognition of the purpose and resolute avoidance of wrong roads, at striking the evil at its root, then the battle against tuberculosis, which has been so energetically begun, cannot fail to have a victorious issue.

## MEASURES FOR THE PREVENTION OF CONSUMPTION. (a)

By Professor BROUARDEL,

Dean of the Faculty of Medicine of Paris, Member of the Institute.

THE mortality from tuberculosis varies according to the country. In some cases it is accountable for a sixth, a fifth, and sometimes a fourth of the total mortality. Havoc such as this makes it compulsory that all nations and governments should strictly inquire into, and adopt, measures to arrest the propagation of a disease which, in these days, is the greatest enemy of the human race. The wonder is that the voice of alarm has been so long in making itself heard, and that for centuries our ancestors have looked impassively on the disasters going on around them. There were several reasons for this apparent indifference. The struggle was considered useless; the disease incurable; it was not known how it spread. Exaggerating the import of some observations, it was agreed that phthisis is hereditary. They were lulled to sleep by this formula, which served as a pillow for idleness and exempted them from investigating the origin of the mischief.

But when, on December 5th, 1865, Villemin showed experiments at the Academy of Medicine, which proved the real presence of the contagion, when our illustrious colleague, Professor Robert Koch, had discovered and demonstrated to the medical world the agent of this contagion, everyone felt that a new way was opened to humanity, and every nation wished to profit for the public good, by the recent scientific discoveries. Before the scientists I have just mentioned had actually made known their discoveries, the English people had already begun the struggle. Convinced by observation that tuberculosis thrived in dark and damp dwellings, in 1836—nearly seventy years ago—you passed a law providing for the construction of healthy houses, and since that date your

zeal has not abated. The grounds for the prevention of tuberculosis are identical in every country. On this question the entire medical profession of the world is united. Tuberculosis is avoidable and curable. With regard to legislation, it is only possible to bring a law into force that interferes with our daily life, that disturbs inveterate habits, and that has to be carried out in the bosom of the domestic hearth, when it is called for by public opinion: when all are convinced of its benefits, and everyone recognises the danger of his vicious habits, and is ready personally to reform them and to require his neighbour to do the same.

Gradually in all countries the public are beginning to realise that personal care and cleanliness are necessary to obviate contagion, and are also realising that other idea, to my mind equally important, that a consumptive patient is only dangerous if the necessary precautions are not taken around him, and if he himself does not take them to protect his relatives, friends, and fellow-workmen from contagion. The danger is in the sputum, which contains thousands of contagious germs. To expectorate on the ground is a disgusting and dangerous habit. Once this habit has quite disappeared, tuberculosis will decrease rapidly.

What rôle does this sputum play in the subsequent propagation of the disease? Collected and shut up in a private, or common but antiseptic, spittoon, destroyed by incineration or some other measure, it is dangerous to no one. Thrown into dry and well-lighted surroundings, exposed to the rays of the sun, it will soon lose its dangerous properties. But if it remains in damp and dark surroundings, it will maintain its activity for a long time. Thus it is that tuberculosis claims more victims from gloomy, ill-ventilated, dark dwellings. All nations have recognised this, but England has the double merit of recognising the primary importance of this problem, and of having solved it in a manner peculiarly her own. Recognising that insalubrious dwellings are one of the most potent agents in propagation of tuberculosis, the legislations of the different countries have kept this cause of insalubrity well in view, and have made laws ordering the destruction of unhealthy dwellings.

If tuberculous germs fall in an ill-lighted, damp house they maintain their activity for a long time, whether the house is in town or country. In these surroundings population is often very dense. It is no uncommon thing to see one room in Paris occupied by five, six, eight, and sometimes twelve persons. They are continually coming in contact with one another, chances of contagion are increased by this fact alone, and in addition to the limited space has to be added the dirtiness of the occupants, or, as I should say, the impossibility of keeping sufficiently clean. The small tuberculous foci are created which invade the whole house; the workmen and employés carry the germs of disease into their workshops and offices and soon make a large tuberculous focus of the town.

The evils of an unhealthy dwelling are not confined to the risk of contagion just referred to. The want of air and light acts on the nutrition of the inmates, children go off, pine away, the strongest men cannot withstand it, every human being living in these places is the destined prey of infectious diseases; and if we only consider phthisis they become predisposing causes of consumption, transforming the strongest man and putting him on a par with the condition of those born of tuberculous parents. In the latter, heredity is not direct; one is not born tuberculous, but predisposed to tuberculosis. Moreover, unhealthy dwellings are not pleasant to pass the time in, and the workman stays

(a) Address to the British Congress on Tuberculosis, July, 1901.

in his home as little as possible, spending the rest of his time in the public-house, and we can add that the public-house is the purveyor of tuberculosis. Alcoholism is, in fact, the most potent factor in propagating tuberculosis. The strongest man, who has once taken to drink, is powerless against it.

Any measures, State or individual, tending to limit the ravages of alcoholism will be our most precious auxiliaries in the crusade against tuberculosis, but the question is too large a one to deal with here.

The dangers surrounding a man in an unhealthy home are the same when for his work, his duties, his pleasure, through illness, or under constraint, he lives all or part of the day in a centre where other people are assembled, where unhealthy conditions and overcrowding exist. If he is well, his companions are dangerous to him; if he is ill, he is dangerous to them. Now the conditions of modern life compel a man to live in such centres. As a child there is the school; as an adult, the barracks; a workman, the workshop; a student, the lecture hall, the libraries, laboratories; the employé or official, the bureau and the offices. If he moves about he uses vehicles, railway carriages, too often contaminated.

At the hotel where he stops he has frequently been preceded by a sick person, and no precautions have been taken to protect the new arrival from possible contagion. If he is poor and ill he goes into a hospital, where he is surrounded by contamination on every hand. This peril from common life, inseparable from advance in civilisation, is continually growing: it is the ransom, and accounts for the threatening increase in tuberculosis.

Before touching on the question of the cure of tuberculosis I should like to say a few words about measures adopted to prevent tuberculous contagion by food. Since Chauveau showed that it was possible for tuberculous germs in food to produce tubercles in the intestinal tract, attention has been turned to precautions for preventing the consumption of meat and milk from tuberculous animals. As far as meat is concerned, surveillance of the slaughter-houses in large towns achieves this. In Belgium this measure is also made to apply to the country; but I do not know of any other kingdom where private slaughter-houses are inspected, and in them it is that phthisical cows, mealy pigs, and diseased animals of any kind are slaughtered, and are able to escape inspection. This injurious food is consumed either as fresh meat, or in the form of pâtés or sausages from which the tuberculous viscera have not been removed. Another danger is the hawking of meat in pieces. It is rife especially in the large towns. Butchers receive daily quarters of meat despatched by provincial butchers. This meat escapes inspection. With no wish to exaggerate the danger of the propagation of tuberculosis by meat, it cannot be overlooked. It is easy, by means of legislation, to protect the population from this method of contamination. Belgium has set us the example. That the milk of cows with tuberculous inflammation of udders is used is very clear.

It is well to add that in large concerns the milk from different sources is mixed, and one cow only need be the victim of tuberculous mammitis in order to contaminate all the milk with which its milk is mixed. To prevent this method of propagation, strict inspection measures should be adopted, such as have been in use for several years in Denmark, Sweden, and Norway, to the great advantage of public health. Until such necessary measures are actually adopted there only remains the simple mode of avoiding risk from milk by boiling it, and this should be widely made known, in spite of a too widespread prejudice, which wrongly holds that boiled milk is less nutritious and indigestible. If a man is

the victim of tuberculosis everything possible should be done to cure him, for *he can be cured*. The idea that tuberculosis can be cured dates back to Hippocrates: "Phthisis, if treated early enough, gets well," said the Father of Medicine.

At the Morgue, in Paris, where I frequently make post-mortems on accidental deaths, I can state that in half the cases, if the person on whom the post-mortem is made has lived in Paris for about ten years, I find healed tuberculous lesions, either in the form of cretaceous transformation or fibrous cicatrization. These lesions, moreover, in the majority of cases, are not phthisis in an early stage manifested by small disseminated foci; they are cicatrices of large foci, sometimes of wide completely cicatrised cavities. Phthisis therefore is curable, even in its most advanced stages. As a tuberculous patient can be cured, everything possible must be done to bring this about by careful organisation. The doctor being himself firmly convinced that his patient can be cured will make the necessary modifications in his way of looking at the disease.

The doctor shall tell the patient and his family at once that he has a serious disease, but that it is curable.

And now as to the methods of treatment. In this address I am only dealing with the disease as it affects working men and employés.

The remedies to be recommended vary according to the stage to which the disease has got, and also if the patient is single, married, or father of a family.

Three distinct periods may be defined. In the earliest the patient coughs and has a cold, and it is this stage of the disease which interests us most, when intervention is of use.

In what way can we be of use to a patient in the first stage? In Germany there are polyclinics for tuberculosis in the large towns, where a doctor, provided with the things necessary, attends to the patients who come to consult him, either throughout their illness, or till the patient can be admitted into a sanatorium. A committee, composed of benevolent men, and women in large numbers, looks after the patient at home, tells his wife what to do, sees that his home is kept clean, and looks after necessary prophylactic measures. As far as possible, the misery consequent on the breadwinner being out of work is relieved from a bank, kept up like the sanatoria banks to assist such cases. Mons. Calmette conceived the same idea, but he went farther, and advised that, instead of waiting for the workman to come for advice, they should go and meet him by inviting him to come to a dispensary, run on the same lines as the German polyclinics.

As far as I can see, the best way to ferret out disease would be to have one or more agent-workmen, foremen-workmen, if it were possible. They are the ones to notice when their comrades cough; they could advise them to go to the dispensary. Alive to the dangers of a badly-kept workshop or yard, they superintend its being kept clean and in order; they actually carry out anti-tuberculous education. Those who visit the dispensary receive the necessary attention from the doctors, and are told the danger of dissemination by sputum, alcoholism, &c. They are looked after, they get meat gravy—one or two meals, as far as funds will allow. Their families are helped and their home is kept an eye on from the hygienic point of view; as far as possible, the misery by which the poor man is threatened is kept away from him. Among these patients some are found who must be sent to a sanatorium. If the patient is an unmarried man, and if he can be sent to a sanatorium, his chances of recovery are very great; but for a married man to go means that his wife and family must be provided for

during his absence, and his mind relieved of all anxiety on their account.

Relief banks for assisting the families of the inmates are most necessary to sanatoria. And in many cases sanatoria are essential to complete the work begun at the dispensary.

All nations have obeyed the same generous impulses, and the time will come when, instead of the poor tuberculous patient being given up to his sad lot, he will find that if he is only in the first stages of the disease, that by means of dispensaries and sanatoria there is always hope and often realisation of his recovery. If the patient is beyond the first two stages when he asks for admission to the hospital, it must not be overlooked that he may still be cured, provided he can be made to see things as they are. He may be isolated, in order that he may not be discouraged by the spectacle of his comrades' sufferings.

I have been asked to consider the question from the international point of view. I do not think that it is possible to deal with consumption in this respect as plague, cholera, and yellow fever have been dealt with in order to prevent their being brought into a country. I do not know how any doctor can state positively that a traveller at the frontier or the port is not consumptive. But it would be possible to take international steps in another way. Railway carriages might be disinfected, as well as steamboats and hotels, and the traveller no longer exposed to germs of contagion. That would be of truly international import. In several countries, particularly in the United States, hotel keepers who receive a consumptive client have to notify it to the municipal authorities, and compulsory disinfection of the room has to be gone through. The Minister of the Interior in Germany has brought in even more stringent measures. Every doctor who attends a case of pulmonary or laryngeal tuberculosis is bound to report it in writing to the police as soon as he has made his diagnosis. After death from tuberculosis the room in which the patient has died has to be disinfected as well as his belongings. Hotel proprietors, "furnished house" keepers, asylums, and other public institutions are compelled to notify at once every case of tuberculous disease which arises in their establishments. Notification, disinfection, salubrity of hotels, carriages, and steamboats, are questions of an international character, which might be advantageously dealt with by representatives of the different nations.

The lesson to be drawn from the efforts that have been made by all nations to carry out a crusade against tuberculosis is that in conversation, in the public prints, and in specially prepared pamphlets, we should make it universally known that tuberculous contamination can be avoided, and that in addition the disease can be cured.

## HUMAN AND BOVINE TUBERCULOSIS. (a)

By Professor MCFADYEAN,  
Of the Royal Veterinary College, &c.

AFTER some preliminary remarks in regard to the supposed identity of the organism of tuberculosis in man and animals, the Professor observed that the view that bovine and human tuberculosis are identical diseases was generally supposed to have been finally determined by Dr. Koch himself, when he discovered that the human and the bovine lesions contained bacilli that were identical in morphological, tinctorial, and cultural characters, and showed

that the artificial cultures from both sources produced indistinguishable effects when they were employed to infect a variety of animals. He pointed out that tuberculin produced a specific reaction in tuberculous cattle, whether human or bovine bacilli had been employed in its preparation. In short, the identity of the bacilli from the two sources appeared to be as firmly established as any other generally accepted opinion regarding the identity or non-identity of bacteria associated with disease in more than one species of animal. Opinions varied as to the frequency with which this transmission of tuberculosis from one species to the other occurred, but practically never within the last eighteen years regarding the possibility and probability of reciprocal infection. What then were the grounds upon which they were asked to discard convictions that appeared to rest on such a solid basis? He would endeavour to state them briefly, as he understood Dr. Koch's train of reasoning:—(1) The bacilli found in cases of bovine tuberculosis are much more virulent for cattle and other domesticated quadrupeds than the bacilli found in cases of human tuberculosis. (2) This difference is so marked and so constant that it may be relied upon as a means of distinguishing the bacilli of bovine tuberculosis from those of the human disease, even assuming that the former may occasionally be found as a cause of disease in man. (3) If bovine bacilli are capable of causing disease in man, there are abundant opportunities for the transference of the bacilli from the one species to the other, and cases of primary intestinal tuberculosis from the consumption of tuberculous milk ought to be of common occurrence. But post-mortem examination of human beings proves that cases of primary intestinal tuberculosis are extremely rare in man, and therefore it must be concluded that the human subject is immune against infection with the bovine bacilli, or is so slightly susceptible that it is not necessary to take any steps to counteract the risk of infection in this way.

He admitted that what may be called bovine tubercle-bacilli are as a rule distinctly more virulent for cattle and other domesticated animals than human bacilli, or that the results of experiments indicate that in natural circumstances there is little danger of cattle becoming infected from human beings. But it could not be admitted that the low virulence of human bacilli for cattle proves, or even makes it probable, that bovine bacilli have only a feeble pathogenic power for man. That might have been held to be probable if it had been shown that bovine bacilli were very virulent only for cattle; but since it is well established that these bacilli are highly dangerous for such diverse species as the rabbit, horse, dog, pig, and sheep, and, in short, for almost every quadruped on which they have been tried, it appeared to be highly probable that they are also dangerous to man. At any rate, it was impossible to cite any ascertained fact relating to other bacterial diseases that made the contrary conclusion probable. It was well known that the majority of disease-exciting bacteria are harmful to only one or two species, but all those that are common to all the domesticated animals are also pathogenic to man. With regard to the view that the difference between human and bovine bacilli in respect of virulence for cattle is of such a fixed and constant character that it may be relied upon to distinguish the one from the other, it need only be said that that was very far from proved. It appeared to be quite possible that what might be called the normal or average virulence of bovine bacilli for cattle might be reduced by passage through the human subject. Besides, there were very great differences in the virulence of tubercle-bacilli found in animals of the same species, and if a low degree for virulence for cattle were to be

(a) Abstract of Address delivered before the British Congress on Tuberculosis, July, 1901.

taken as the distinguishing feature of human bacilli, there would be no difficulty in proving that the human disease is sometimes transmitted to the lower animals.

The third proposition in Dr. Koch's argument was the only one which was really germane to the point at issue, viz., that only cases of primary intestinal tuberculosis can possibly have had their origin in infected milk or meat, and that "such cases are extremely rare." Dr. Koch referred to several series of post-mortem observations that appeared to justify this statement, and added that he could have cited many more pointing to the same conclusion. He pointed out that statistics were not by any means unanimous, and those that were likely to appeal with most force to the people in this country were not at all in accord with those quoted from Germany. During the last few years the evidence obtainable from the post-mortem records of two of the largest hospitals for children in this country had been analysed with great care, in order to see what evidence they afforded as to the relative frequency of the different methods of infection in tuberculosis. In the case of the Hospital for Sick Children in Great Ormond Street this had been done by Dr. George Still, and in the case of the Royal Hospital for Sick Children in Edinburgh by Dr. Shennan. The conclusion at which Dr. Still arrived was that in 29.1 per cent. of the cases of tuberculosis in children primary infection appeared to have taken place through the intestine. That was very far from being an insignificant proportion, and it was a striking fact that Dr. Shennan arrived at an almost identical conclusion, and estimated that 28.1 per cent. of the cases of tuberculosis among children in Edinburgh are due to alimentary affection. In face of these statistics it was not possible to assent to the statement that cases of primary tuberculosis of the alimentary canal are extremely rare. Precisely the contrary conclusion was the one that must in the meanwhile be drawn with regard to the state of affairs in this country, viz., that, at least in children, primary infection by way of the alimentary canal is comparatively common. In respect of the proportion of these cases which ought to be ascribed to tubercle-infected milk, he recalled the fact that the late Sir Richard Thorne Thorne, in the Harben Lectures on the administrative control of tuberculosis, which he delivered in 1898, expressed his conviction that tuberculous milk was the main cause of *tabes mesenterica* in children, and he characterised the loss of child life from this cause as appalling. On the strength of the Registrar-General's returns, which showed that during the last fifty years there had been a marked decline in the death-rate from human phthisis, which is the form that tuberculosis generally takes when the bacilli are inhaled. On the other hand, during the same period there had been only a slight decline in the death-rate at all ages from that form of tuberculosis which is ascribable to alimentary infection, and among children under one year of age there had been a notable increase in the mortality from that form of the disease, which he attributed to infection through milk, which had remained unchecked. He was, however, prepared to admit that there were several weak points in this argument.

He pointed out that about 30 per cent. of all the cows giving milk in this country were tuberculous in some degree, and about 2 per cent. of the cows had tuberculous udders. Now, the milk secreted by a tuberculous udder always contained tubercle-bacilli, and it sometimes contained enormous numbers of them, and when these facts were apprehended one began to realise the seriousness of the danger to which, in the present state of affairs, those who drink uncooked milk are exposed.

The Professor concluded his remarks by urging the necessity for educating the public in the nature of the disease, and of instituting a system of inspection of cows. He insisted on the fact that the inhalation of tubercle-bacilli expelled from the bodies of human patients was doubtless the great cause of human tuberculosis, and every practicable means of preventing infection in that way ought to be employed; but, at the same time, they ought not to concede to the milkmen the right to sell us tubercle-bacilli, even if we were assured that—like Dr. Koch's experimental pigs—we had nothing to fear beyond the development of "little nodules here and there in the lymphatic glands" of our necks and "a few grey tubercles" in our lungs.

## REMARKS ON THE DEGENERATIONS AND COMPLICATIONS

OF

### UTERINE MYOMATA. (a)

By H. MACNAUGHTON-JONES, M.D.,  
M.A.O., M.Ch., &c.

It is unnecessary for me to remark that the importance of a subject connected with the degenerations and associated complications of uterine myoma can hardly be exaggerated; it is the turning point upon which future practice will in great measure depend. I have gone to the trouble of having the museums of some of the largest London hospitals searched with reference to the subject, and also the museum of the Royal College of Surgeons. The point I wish to make is that gynecologists are really beginning a new era in connection with that disease. The great majority of specimens shown at various societies are presented as proofs of the operator's skill and dexterity, and no doubt are interesting from their size and from the point of view of technique, as illustrating the difficulty of removal. Numbers of these tumours have been looked at and not even opened, and without any report having accompanied them as to the pathological nature of the growth removed. Countless numbers of valuable specimens must have been destroyed as useless which would have materially altered the view which has been taken with regard to the treatment of myoma if these had been preserved and reported upon.

In the Museum of the Royal College of Surgeons of England there are in all 47 specimens marked definitely as fibrous tumours of the uterus. Of these, 33 are described as having undergone ulceration, degeneration, or been complicated by adhesions, pregnancy, or ovarian tumours. These we may divide as follows:—Pressure of ureters, 1; ulceration of the tumour, 3; ulceration of the vagina, 1; calcification, 3; cystic degeneration, 1; with complications of the adnexa, 6; with pregnancy, 5.

In St. Bartholomew's Hospital Museum there are examples of the following degenerations and complications:—Cystic degeneration, 3; calcification, 2; myoma complicated with diseases of the adnexa, 5; myoma with cancer, 1; degenerating myoma with cavity containing serous fluid, 1.

In University College Hospital Museum there are the following:—Sloughing myoma, 1; fungoid degeneration with ulceration, 1; suppurating myoma with calcareous degeneration, 1; calcareous degeneration with adnexal complications, 2; calcareous degeneration alone, 5.

In the Westminster Hospital Museum there is 1 specimen of calcareous degeneration. In St. George's

(a) Remarks made in opening the Discussion on Dr. Charles Noble's paper at the British Gynecological Society, on July 11th, 1901.

Hospital Museum there are 4 specimens of calcareous degeneration of myoma, 2 of myoma complicated with pregnancy, 1 of myxomatous degeneration, and 1 of fibro-cystic degeneration.

In King's College Hospital Museum there were none. Mr. Cheate has kindly lent me one of carcinoma and myoma.

In St. Mary's Hospital Museum are the 6 specimens exhibited here to-night.

Those from the Cancer Hospital were also before the Society, 10 in number (Mr. Jessett's).

I think that the inference is clear from the enormous number of cases which must have passed through these hospitals, that a huge mass of material has been unobserved or unrecorded.

In future I trust that specimens which are presented of myoma or of complicated myoma will be accompanied by a proper pathological report, not only setting forth the inherent characteristics of the tumour itself, but the adnexal or other complications that have been associated with it. Then gynecologists will have something definite to rely upon.

Dr. Charles Noble, in his paper, has referred to the menopause. I take it that no one now advances the argument that the danger of a myoma is lessened by the menopause. On the table is a tumour which I exhibited at the Society, removed from a woman who had been suffering from profound anæmia, so bad that it was with great apprehension I thought of operating upon her. The woman was restored to perfect health. There had been mucoid degeneration, and the tumour, a multiple myoma, weighed eight pounds. A very important point about the menopause is the following. We speak of climacteric insanity; and if there be one point settled among psychologists more than another it is the fact that myoma has very frequently a distinct effect on the mentalisation of the woman. Of that I have no doubt whatever. I have seen two or three instances of actual dementia, and one of mania complicating myoma at the menopause. There is thus a distinct danger at this time, a point not dwelt upon by Dr. Charles Noble as fully as it might have been. One must consider carefully the mental effects of the tumour on a woman, not only from the constant introspection induced by the presence of the tumour, but also the constitutional and other conditions, including profound anæmia, which Dr. Noble has referred to.

Dr. Noble has said in his paper that the penetration of the capsule of a fibroid by adjacent carcinoma is very rare. On the table is a specimen of mine in which that invasion is manifested. There is a distinct passing in of the carcinomatous tissue into the myomatous growth. I admit that the condition of sarcomatous degeneration does occur, but it is very rare.

Another point I wish to allude to is borne out by a specimen of mine on the table, where there is a tumour resembling adeno-myoma of the uterus, in which there is complicating it adeno-myoma of the ovary. And so closely does that assume malignant characteristics that a special Committee was appointed to investigate it. The decision arrived at was that it was adeno-myoma. It illustrated another serious consequence of myoma. When a woman arrived at a certain time of life, if she has pain in walking and on taking exercise there ensued a deterioration of her general health, and thus in a certain proportion of cases of myoma the first thing the woman complains of is that she cannot walk. The patient in question had such pain in the hip that there was a strong suspicion of joint disease. The myoma was discovered. The adeno-myomatous ovary was found at operation jammed down on the nerve, causing the pain and lameness.

In regard to cardiac complications it is right to

mention that a Fellow of the Gynecological Society fifteen years ago drew attention particularly to the complications of myoma with cardiac conditions, namely, Dr. Bedford Fenwick, in a paper which he wrote on the subject.

Another very important matter which is often forgotten in connection with these tumours is the question of mistaken diagnosis. It is all very well to take it for granted that a myoma when it occurs is always diagnosed; but in many instances it is not correctly differentiated or diagnosed. Other tumours are constantly mistaken for myomata, and by the most experienced gynecologists. Sarcomatous and carcinomatous ovaries had often been mistaken for myomatous tumours, and thus, under the idea that the tumour is harmless, interference is postponed until operation becomes impracticable, or possibly death intervenes to settle the question.

I believe the crucial point is not the percentages which can be brought forward by an operator to show his skill and the ease with which such tumours can be removed. These are now matters of ancient history. What we have to decide is our attitude to the treatment of these growths in consequence of the pathological fact which cannot be denied, that many of the tumours contained in themselves or in their complications, the inherent elements of future death, or at all events of invalidism, of misery in life, to many of torture, and the rendering of the woman useless to herself, useless to her family, and useless to society. Such a woman is an opprobrium to the surgical art.

## Clinical Records.

### BRADFORD UNION HOSPITAL.

NOTES ON A

#### *Case of Idiopathic Gangrene of Penis.*

By JOSEPH BEARD, F.R.C.S.E.

In November of last year I admitted a man, Robert C., æt. 52, into this hospital, suffering from lobar pneumonia. He was extremely ill and disinclined to answer questions.

On examination I found him suffering from acute lobar pneumonia of right lung, and in a very weak and collapsed condition, his heart sounds being scarcely audible, breathing very difficult and shallow, with anæmia in active condition. Temperature 101° F, pulse 100, hard, small, and irregular. Respiration 30 per minute. On further examination I found that he had something wrong with his penis, which he said began to go black five weeks before and began to burn and pain him when he passed urine.

This organ was now in a state of total dry gangrene, black and shrivelled up, and close to the putes was a well-marked line of demarcation which above and at the sides had ulcerated through the skin and areolar tissue down to the corpora cavernosa. On the under aspect, where it was somewhat moist with the passage of urine over it, the ulceration had extended through the corpus spongiosum and through the urethra. I passed a catheter through the proximal portion of the urethra into the bladder and drew off 3 ozs. of urine, which had a specific gravity of 1015, and contained albumen and sugar and was acid in reaction.

Next morning his condition was worse, and he was in a semi-comatose condition in spite of treatment.

At noon I infused 50 ozs. of saline solution into his median basilic vein. He rallied for a couple of hours, and then died comatose.

I obtained permission for a post-mortem examination, which revealed extensive degeneration of arteries chiefly. In fact, with the exception of the cerebral arteries every visible artery was markedly calcareous, and on dissecting out the dorsal arteries of the penis they were extremely tortuous and reduced to mere brittle cords, which broke when touched.

The pneumonia was verified, and the heart was soft and

toneless. The liver was the organ showing most change of a pathological nature, being hard and fatty, weight 70 ozs. The bladder was very enlarged, and easily held 60 ozs. of water. The other organs were in fair condition. Pancreas was perfectly normal to the naked eye.

I should mention that the man told me that for some months he had been passing large quantities of water, and that he was always thirsty.

Death in this case, of course, was due to heart failure, secondary to the acute pneumonia, but that would not account for a gangrene of the penis of five weeks' duration, and if asked for the solution I should say that the gangrene of the penis was due to the arterio-sclerosis following upon diabetes mellitus.

True idiopathic gangrene of the penis is a very rare disease, and Demarquay, who specially directed attention to it, found but few instances of it in the records of surgery.

Gangrene is not uncommon in diabetes, and is associated especially with arterio-sclerosis. Wm. Hunt analysed 64 cases, and in 50 the localities were as follows:—Feet and legs, 37; thigh and buttock, 2; lungs, 3; nucha, 2; external genitals, 1; fingers, 8; back, 1; eyes, 1.

## Transactions of Societies.

### BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD JULY 11TH, 1901.

The President, Dr. J. A. MANSSELL MOULLIN, in the Chair.

#### EXHIBITION OF SPECIMENS.

THE PRESIDENT drew attention to a number of interesting specimens brought together by Dr. Macnaughton-Jones, and exhibited in reference to Dr. Noble's paper. The collection included tumours which had undergone calcareous, cystic, mucoid, and teleangiectatic degenerations, others which were entirely œdematous, or into which hæmorrhage had taken place, several complicating pregnancy, and several in which, in addition to the myoma, a carcinoma, sarcoma, or cysto-sarcoma was present.

Dr. CHARLES P. NOBLE, of Philadelphia, read a paper on

#### THE COMPLICATIONS AND DEGENERATIONS OF FIBROID TUMOURS OF THE UTERUS,

which we published in full last week.

Dr. MACNAUGHTON-JONES then opened a discussion on the paper. His remarks will be found on p. 111 of our present issue.

Mr. BOWREMAN JESSETT, who followed, remarked that the Fellows of the Society were much indebted to Dr. Noble for having come to this country to deliver his admirable address. While not by any means advocating the removal of all myomatous tumours, he (Mr. Jessett) could not help thinking that the excessive conservatism of some leading obstetricians was detrimental to the best interests of women. Four years ago he curetted an uterus, and the material removed from the fundus proved to be carcinomatous. He then removed the growth, which had not since recurred. The patient in this instance had suffered for two or three years from successive hæmorrhages, and yet had been assured, or at any rate encouraged to believe by more than one obstetrician in a leading position, that the tumour would disappear at the menopause. In skilled hands the mortality after operation for myomata should be less than 5 per cent., and he thought that this low rate of mortality was in part due to the late Mr. Lawson Tait, inasmuch as he first ceased the indiscriminate administration of opium, and gave an aperient two days after operation. With regard to complications, he had seen a case of appendicitis closely simulate ovaritis, but he had never seen the former as a complication of myoma. He could not agree with Dr. Noble as to the rarity of sarcoma. He had at least four specimens showing the presence of sarcomatous cells, two of which were before the Society. As

to carcinoma, he had not seen more than two or three cases, and was inclined to think that where present with a myoma there was no relationship between them. The question of pregnancy might be a very serious one. On one occasion on which he found two large fibroids, and suspected pregnancy, he advised the woman to postpone any active interference. Three weeks later the patient was taken suddenly ill, had a severe rigor, and appeared in great danger. He performed hysterectomy and found a fetus present, with two fibroids. The patient made an excellent recovery. He would remark, however, that if the patient goes to full term and is delivered safely, the fibroid becomes reduced in size. When operation was necessary he considered the removal of the uterus to be preferable to abortion. The question of the effect of the menopause had been worn threadbare. In a few cases tumours decrease in size, while in some they undergo a marked increase. There were two other points which should be borne in mind when considering the advisability of operation—the social position of the woman and the situation of the tumour. A tumour might incapacitate a poor woman from obtaining a livelihood and consequently call for operation, whereas in the case of her wealthier sister it might occasion inconvenience only. Sub-peritoneal fibroids grew less quickly, and caused less urgent symptoms than those of submucous or intra-mural origin, and therefore rendered operative interference less necessary. When, however, severe hæmorrhage occurred, the patient became anæmic and lost strength, or sepsis supervened, operation should be resorted to as early as possible.

Mrs. SCHARLIEB believed that a certain number of fibro-myomata did decrease in size at the menopause, yet waiting for that event, and the very problematical benefits produced by it involved serious risks. In this connection she quoted the case of a lady, considerably over fifty years of age, with an apparently quiescent myoma reaching to the level of the umbilicus, who had consulted her twelve months or more previously. The patient had passed the menopause and was in a fair state of health. She promised to return in a short while, but failed to do so. Recently she had been called to her in response to an urgent summons, and found her suffering from pleurisy, thrombosis of both femoral veins, and severe abdominal pain and sickness. Her pulse was rapid and her temperature 102° to 105°, her whole condition indicating that there was considerable septic absorption, and being such as to render immediate surgical relief hardly practicable. After the lapse of a month her condition had somewhat improved, and Mrs. Scharlieb removed the myoma which contained several cavities filled with offensive fluid. The patient made a complete though tedious recovery, and Mrs. Scharlieb regretted she had not advised operation when she had first been consulted. As to age, Mr. Noble's youngest patient was 17. She had removed with Mrs. Stanley Boyd, a tumour from the anterior wall of the uterus of a girl, æt. 14, brought the edges of the incision in the muscle together, and left the patient with her uterus, ovaries, and tubes complete.

Mrs. STANLEY BOYD referred to the great difficulty of determining the original nature of a tumour said to have undergone sarcomatous degeneration, especially in hospital patients who usually came with a tumour already large. For example, a patient, æt. 50, recently came under her observation with a large tumour producing severe hæmorrhage. From the fact that it had first appeared six months after the menopause, and from the rapidity of growth, it was suspected to be of a sarcomatous nature, and such it proved to be. In such a case it was not possible to say whether the growth was sarcomatous *ab initio*, or had been a fibroid at an earlier stage, and had recently become sarcomatous, and, consequent on the change, had grown rapidly and become evident. Curetting she regarded as an extremely unsatisfactory method of arresting the hæmorrhage produced by a fibroid. Its effects were never permanent.

Dr. HAYWOOD SMITH thought that fibroids did undoubtedly decrease after parturition, though possibly there was an initial increase during pregnancy. He thought the surgeon might with advantage avoid inter-

fering were pregnancy a probable contingency, and if the uterus were not much enlarged, or if the tumour were flattened. Curetting should be entirely suppressed in cases of fibroid tumour.

Dr. HERBERT SNOW said there were four ways in which a fibroid tumour of the uterus might be related to malignancy, only one of which could properly be spoken of as a process of degeneration. A tumour might be of the soft, solitary, œdematous variety. These began at an early age, were always attended by hypertrophy of the uterus, and in their later stages by an immense secretion of serum, so that the tumour on section lost about one-fourth of its bulk. At the last meeting he had suggested the term "monoma" for such tumours. They were malignant from their first appearance, inasmuch as, though not of a sarcomatous nature, they invariably proved fatal in a comparatively short time, unless removed. Then there was the common, hard, multiple fibroid, which in a few rare instances became myo-sarcomatous. Such a change might truly be spoken of as degeneration. Thirdly, a myoma might be present, merely as a coincidence, in a uterus in which there was a carcinoma. Lastly, a myoma might, by the irritation and congestion which it produced, induce the development of carcinomatous disease. In reference to the causes of death, he agreed with Dr. Noble and Dr. Macnaughton-Jones as to the importance of early operation, and of not relying upon any beneficial results which might follow the menopause. At the same time he would point out that a number of corpulent women of advanced age had multiple myoma which apparently produced no symptoms.

Dr. MACPHERSON LAWRIE believed that fewer operations would be performed for myoma uteri in years to come than at the present time, though in poor women he quite agreed that operative measures might be more frequently necessary.

Mr. SKENE KEITH pointed out that when a fibroma was present the menopause rarely took place before the age of 54. He was convinced that fibrous tumours did diminish in size after pregnancy. He recommended operation in a certain number of cases, but he held very strongly that the majority of fibrous tumours of the uterus did not require operation.

Mr. STANLEY BOYD said that the etiology of certain complications was obvious, as for example, necrosis, and other changes described as taking place in fibroid tumours. Again, inflammation might easily spread from the uterus to the Fallopian tubes, and endometritis be followed by salpingitis, the contents of the tube becoming subsequently infected with pyococci or the bacillus coli communis. But such a condition as cancer could hardly be regarded as a complication, it being of epiblastic origin, while fibro-myomata were of mesoblastic. Though it was conceivable that the irritation produced by a myoma might give rise to cancer, he did not believe that increased vascularity tended to do so, seeing how very much more vascular other regions were without increased liability to such a change. No developmental difficulty presented itself with regard to sarcomatous degeneration. Mesoblastic tissue already growing abnormally might, without violating the laws which embryology seemed to have established, become malignant in nature.

Dr. NOBLE, in reply, said that one point he had endeavoured to emphasise by his paper was that a fibroid tumour should not be regarded as an isolated entity; but in conjunction with the many complications with which it was in a large percentage of cases associated. He did not maintain, and it was not his object to establish, that if a woman had a fibroid she necessarily developed appendicitis, ovarian disease, cancer, etc., but merely that in his experience, and as far as he could ascertain, in the experience of others who had equally carefully recorded their cases, in any 100 cases in which fibroid tumours were taken just as they presented themselves without selection, some other disease would be present, and that that fact had a very material bearing upon the line of treatment which should be followed. He agreed with Dr. Macnaughton Jones that where a fibroid tumour had been long present, and the patient anæmic,

the mental condition of the patient was not normally stable. He thought the term "expectant" should replace the word "conservative" as applied in gynecology. As to sarcomatous degeneration it was a question for pathologists to decide, but he had been assured by those in whom he reposed much confidence, that true sarcomatous degeneration was very rare. He quite agreed with Dr. Heywood Smith's remarks on curetting, and regarded it as palliative at best.

PARIS, July 28th, 1901.

### OPHTHALMIA NEONATORUM.

At the Académie de Médecine M. Pinard read a paper in answer to a circular received from the Government on the prophylaxis of ophthalmia in new-born infants, in which, after developing the subject, he proposed the following resolutions to be approved by the Académie:—

1. To distribute in all the town halls, with the birth certificate, a short notice indicating the causes, symptoms, and dangers of ophthalmia of infants.

2. To take measures for the immediate notification of purulent ophthalmia everywhere, and in every case.

3. To attach to all the maternity hospitals and clinics oculists charged with the direction of the treatment of purulent ophthalmia, and the instruction in the affection of students, doctors, and midwives. (Adopted.)

### TREATMENT OF JUVENILE ACNE.

Bicarbonate of soda, grs. vj;  
Calcined magnesia, grs. iv;  
Powder of cascara sagrada, grs. iij;  
Benz. naphthol, grs. iij.

For one wafer. Two a day at meal times.

Naphthol B., grs. vj;  
Resorcine, grs. iv;  
Savon noir, grs. iv;  
Prepared chalk, grs. x;  
Sublimated sulphur, grs. xxx;  
Vaseline, ʒvj.

To be used at night.

Each morning pass over the face—

Borate of soda, ʒiij;  
Camphorated sulphuric ether, ʒij;  
Eau de roses, ʒix.

### CACODYLIC MEDICATION.

M. Gautier read a paper on the above subject, in which he established that the preparations of cacodylate of soda administered by the hypodermic method rendered good service in consumptive affections such as pulmonary tuberculosis in the first and second stages, osseous tuberculosis, diabetes, neurasthenia, chronic paludism, pronounced anæmia, &c.

The principal counter-indication to the use of the drug lay in hepatic affections, cancer, congestion, hypertrophy, jaundice, cirrhosis.

The symptoms of interference were intermittent congestion of the face, sensation of pain in the abdomen, rarely fever.

In women the cacodylic treatment hastens the return of the menses and renders them more abundant. Sometimes even metrorrhagia is provoked if the agent is not suspended four or five days before the appointed time.

One of the surest signs that the proper dose has been exceeded is the noises in the ears complained of by the

patient. The cacodylates can be employed for any length of time provided they be suspended from time to time. They acted by exciting the reproduction of the cells in multiplying the hematin, in rejuvenating the tissues, and in conferring on the economy an extraordinary resistance to morbid affections.

Amongst the adjuvants of cacodylic medication iodides take first place. The speaker advised the administration to the patient an hour before dinner a dessert spoonful of a solution containing one drachm of chloride of sodium, fifteen grains of iodide of potassium and of bromide of potassium in three and a-half ounces of water.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 27th, 1901.

In the *Archiv. f. Gyn.*, Bd. 63, C. Menge has a very practical article on the

#### TREATMENT OF CHRONIC ENDOMETRITIS IN GENERAL PRACTICE.

He believed the reason why this disease is so much neglected by the general practitioner lies in the want of technical dexterity. The writer was led by this conviction to search out a method of treatment that would be equally useful in all forms of the disease, that would be as free from danger as possible, and that would demand the least possible amount of manual procedures. The treatment should admit of being carried out rapidly in the consulting room, and without previous dilatation of the cervix. After touching upon the usual methods of treatment, he proceeded to describe that practised by himself, which in the course of years has proved to answer all the requirements both on the side of the general practitioner and of the patient. A solution of formaline, from 30 to 50 per cent. in strength, has proved a useful and non-painful intra-uterine application. For the purpose of applying such a solution he has had constructed a smooth, hard rubber sound, thinner towards the end, armed with a thin layer of absorbent cotton to a distance of 40 ctm., and kept for use in a cylinder filled with the formaline solution. The caustic is never applied after a bimanual examination, but always some days afterwards. It is applied in the following way: A freshly boiled Trelat or Neugebauer speculum is introduced into the vagina. After the os is found it is wiped with a pledget soaked in perchloride solution. The anterior lip of the uterus is now hooked for the purpose of steadying it—not to draw it down. Two or three formaline sounds are now introduced one after the other and passed in all directions, so that the bottom of all the folds of mucous surface shall be reached. A strip of gauze is now introduced for the purpose of draining the cavity of superfluous fluid. In the early part of the treatment it is best to wait until the mucous surface is renewed before applying the caustic a second time. Later on, however, it may be applied at intervals of a week. The formaline caustic had a beneficial effect in chronic endometritis whether following labour or abortion, provided that no placental remains were in utero. These should not be burnt off with the caustic, but after one or two applications they should be removed with the cuvette. Post-gonorrhoeal endometritis may often be cured in this way after very

few applications, provided general treatment be kept up at the same time. If, on the other hand, the endometritis is due to general disturbance, but little is to be expected from local treatment. There must be a rational combination of general and local treatment in some cases. He mentions the contra-indication to the treatment, which will be obvious to anyone who gives the matter a thought. When there is malignant change in the endometrium the treatment is inadvisable.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 27th, 1901.

#### KNEE-JOINT CONTRACTIONS AND ANKYLOSIS.

At the meeting of the "Naturforscher" Lorenz gave his experience of 300 cases which had been treated operatively for correction of knee-joints by rational orthopedics. There are two fundamental principles which he considers should always be kept in view—correction of the vertex of the deformed angle and rigid protection of the skeletal parts, even at the cost of the soft tissues. In straightening the limbs he prefers the use of a caoutchouc upholstered plate or pad—"Lorenz Redresseur." This instrument is fitted on to the lower part of the femur, the padding stops at the knee-joint; from this a fixture passes on to the tibia, and is also, by means of a screw, slowly pressed outwards and downwards until the leg is straight. This usually termed central correction.

When the injury is eccentric and much of the soft tissue destroyed, the correction may be effected more rapidly, gradually altering the apparatus every three quarters of an hour. He summarises the advantages of this operation as: freedom from danger; retention of all the skeletal strength, easy locomotion, as well as a final mobile joint. During the last five years he had treated 300 contracted and ankylosed knee-joints with the best results.

In the discussion that followed Muller expressed surprise that Lorenz never speaks of having awakened new inflammatory action in a joint that has been quiescent, as most of these ankylosed joints occur in strumous or tuberculous patients prone to this new evolution.

Lorenz replied by saying that his practice was not to touch a joint until all inflammatory action had ceased.

#### LUXATIO PATELLÆ.

At the same meeting Bardenheuer described his mode of procedure when the patella became habitually luxated. He lays the knee-joint bare without opening it. By a crescentic incision the capsule is opened on the inside, the ligamentum patellæ proprium is divided, while the posterior part of the capsule is drawn forward over the anterior portion and fixed with a suture, while the whole is finally attached to the vastus internus. The inner margin of the biceps tendon is often turned over and fixed, thus shortening this muscle also.

Trendelenburg thought that most of the habitual luxations were congenital, particularly the genu valgum, which was best treated by McEwen's operation. In one case recently, after trying many remedies, he found the tuberosity of the tibia with the ligamentum patellæ, and finally made a groove with the chisel over the front of the external condyle, into which he drove an ebony

wedge. He is unable yet to say what the final effect may be, although the method answers well at the present.

#### INJURY TO THE CENTER OF SPEECH.

Longard showed two cases to the meeting where complicated fractures of the left parietal bone had taken place two to three centimetres above the ear. In the first case speech was almost lost for fourteen days after the injury, which might correctly be termed monophasia, as every question was answered by "Bitte, Bitte," the patient having no power to say more. For six weeks after the accident he gradually improved, so that after that time speech had so far recovered as would lead a stranger to believe that nothing had occurred. No paralysis or other untoward symptom was present, which was strange after losing upwards of a tablespoonful of brain matter from such an important part of the brain as the central convolution. At the time of exhibition nothing defective could be observed.

The second case had slight paresis of the right upper arm and a little spastic step, motor aphasia, and agraphia. Three weeks after the accident he suffered from traumatic delirium, which soon passed off and has left him perfectly well.

#### CYSTS IN OVARIAL REMAINS.

Fischer and Waldstein in Schauta's clinic have recently drawn attention to the frequency of cysts forming in the remains of the adnexa after tubes and ovaries have been carefully removed. Fischer relates a case as an example where both tubes and both ovaries were carefully removed. The following year he had to remove a cyst about the size of his fist, and one from the right side the next year.

Waldstein records four such cases of his own that had to be operated on again at different periods after the primary operation for cystic recurrence. It has been observed that these remnants have power sooner or later to develop cysts until perfect atrophy has destroyed cystic degeneration.

#### LIGATURES AND SUTURES.

Catgut has not given the satisfaction to surgeons that would inspire confidence, hence the search for some substitute. Katzenstein has introduced an instrument for applying silver wire in the form of rings, for which he claims many advantages.

Greife, of Moscow, has discovered that the hair of the reindeer is perfectly germ free, and an excellent substitute for catgut. To remove the fat the hairs are placed two days in ether, subsequently in oil of juniper, alcohol, and sublimate.

### Special Article.

#### THE CONGRESS ON TUBERCULOSIS.

THE organisers of the Congress which ran its normal course last week may be congratulated upon having done their work well. The whole machinery moved smoothly and we have heard no complaints of short-comings, not even from our fellow preesmen, who are usually, and not unreasonably, prone to criticise. Professor Koch's paper, which we publish elsewhere, on the non-identity of bovine and human tuberculosis had for effect to throw into the shade many valuable contributions dealing with, or based upon, the views which the eminent pathologist has challenged. It is obviously idle to discuss the degree of infectivity of milk and meat

at a time when the infectivity itself is called in question, nor do measures for sterilising, or preventing the sale of, such aliments commend themselves for discussion when, it may be, they will shortly be proved to be unnecessary. In the feeling of surprise at Professor Koch's unexpected announcement, which will remain the *clou* of the Congress, one is apt to exaggerate the importance of the point at issue. Whether the bovine disease be communicable to man or not, no one doubts that man to man infection is by far the most important means of propagating the disease, and we must act accordingly. We were possibly in danger of overlooking the vastly greater scope of human infection in our endeavours to prevent contamination of animal origin.

Now at any rate we have no excuse for failing to grapple the problem in a scientific spirit. We know that the expectoration of tuberculous subjects is the prime source of infection, and it is for us to devise plans for depriving this agency of its lethal power. The plan of campaign comprises several general principles and a number of precautions of detail. An united effort must be made to prevent promiscuous expectoration, less by repressive legislation, which would be difficult to obtain and still more difficult to enforce, at any rate so far as the streets are concerned, than by impressing upon the public the benefit to the community which would accrue were this disgusting habit voluntarily put a stop to. The next point is to remove phthisical patients of the working classes from their unsanitary surroundings, partly with a view to preventing the spread of the disease to other members of their families, partly also with a view to their cure. We must bring our influence to bear upon our consumptive patients to induce them to prevent their becoming a source of danger to the community. This can be done by telling them what to do and what not to do, and also by furnishing them with a portable spittoon. These recommendations, so far as they go, will commend themselves as easy of application and of undoubted efficacy. When, however, we come to consider the conditions under which human beings fall a prey to the disease we are confronted with difficulties of another order. Susceptibility to tuberculosis may be inherited or acquired. Hereditary predisposition may be minimised by careful attention to the laws of hygiene, but there remains the fact that the circumstances and conditions of labour of the labouring classes, at any rate in our large cities, are often such as to favour the evolution of the disease. Overcrowding, want of cleanliness, alcoholism, imperfect ventilation, &c., all tend to depreciate vitality and so throw open the doors to infection. Here we are face to face with a problem of such immensity and complexity as to discourage all but the most robust. Legislation has done much to ameliorate the conditions of life of the working classes, but how much more remains to be done! Still, though it may not be possible to cleanse the Augean stables forthwith, it behoves us to attack the problem resolutely and persistently. The danger is not confined to any one class of the community, for society may be likened to an organism which suffers as a whole when one of its organs is diseased.

Among the questions discussed was the system of voluntary notification of cases of phthisis. Obviously it would be idle to adopt notification unless this step

were to be the prelude to further steps. And what are these steps? Apart from the fact that a knowledge of the local distribution of phthisis would call public attention to the prevalence of the disease in certain areas, thus inviting more efficient sanitary inspection, it would enable the sanitary authorities to give advice as to the sterilisation of the sputum, and to secure the removal to sanatoria of those whose circumstances are such as to preclude adequate care at home. It would enable them to insist upon thorough disinfection of the premises and the remedying of obvious sanitary shortcomings. The opinion of Congress was in favour of its adoption wherever it was practicable to take the consequential measures.

There was a good deal of discussion on the question of compensation to breeders and others for the slaughter of animals recognised to be tuberculous, but in future it is probable that only animals suffering from general tuberculosis will be condemned, in accordance with the general principle that the meat of diseased animals shall not be sold, so that the question of compensation will hardly be brought forward. The owner of a diseased animal cannot expect to be recuperated from public funds any more than he himself would claim compensation when from illness he is unable to attend to his business.

Incidentally attention was called to the importance of providing better accommodation for cattle. They, like human beings, suffer from overcrowding, inadequate ventilation, and insufficient nourishment. The importance of the segregation of infected animals is as important with animals as with human beings. It is to neglect of cattle hygiene that we owe the fact that over half the total number of cows in this country suffer to a greater or less degree from tuberculosis. That is a deplorable fact from a merely commercial point of view, and breeders of animals must be made to understand the importance of maintaining their cattle in a good state of health quite apart from any question of their communicating their disease to human beings.

The concluding general meeting took place on Friday, when a number of resolutions were agreed to. (1) Recognising the extremely infective nature of tuberculous expectoration, and in favour of suppressing promiscuous expectoration; (2) urging that patients with phthisis should be provided with a portable spittoon and given printed instructions of the precautions they should take; (3) affirming the good results to be obtained by voluntary notification if utilised to prevent the spread of the disease; (4) recognising that the provision of sanatoria is an indispensable part of the measures necessary to the diminution of tuberculosis; (5) urging medical officers of health to continue their efforts to prevent the spread of tuberculosis by meat and milk, (6) urging the Government to set on foot an inquiry in view of the doubts thrown on the identity of human and bovine tuberculosis. Passing over several resolutions of subsidiary importance the Congress recommended the creation of a permanent International committee to co-ordinate the labours of the various bodies having for object the advancement of the cause.

The Congress indisputably owes much of its success to the cordial support which His Majesty has given to the movement. The foreign delegates were received by His Majesty at Marlborough House on Thursday last, when he thanked them for their co-operation in the good

work, and called their attention to the fact that cancer was another fell disease which had so far baffled the scientific and medical men of the world.

Every evening during the week there was some function of interest to occupy our distinguished visitors. On Monday the President of the Council, the Earl of Derby and the Executive Council held a reception. On Tuesday the Lord Mayor and Lady Mayoress received the members and delegates at the Mansion House. On Wednesday evening the Countess of Derby and the Ladies' Reception Committee gave a garden party at the Royal Botanical Gardens. On Thursday Lord and Lady Derby had a reception at the Victoria and Albert Museum. On Friday afternoon Sir J. Whittaker Ellis invited the members to a river party at Richmond; while on Saturday afternoon, as a graceful close to the proceedings, the Duke and Duchess of Northumberland gave a garden party at Syon House.

## The Operating Theatres.

### ST. THOMAS'S HOSPITAL.

MR. BATTLE'S OPERATION FOR FEMORAL HERNIA.—Mr. BATTLE operated on a young man, *æt.* 21, for the radical cure of left femoral hernia. There were many unusual circumstances attending the case, which rendered a diagnosis of the swelling difficult. The patient stated that he had noticed the tumour suddenly about two years before, that it was the same size then as it was on admission, that it had not varied in size on any occasion since it had appeared; he had had no pain or discomfort about it, and in fact it caused him no inconvenience. The tumour, situated in the left groin, occupied the femoral region, it was flattened, of somewhat irregular outline, appeared lobulated, and had a fairly defined margin. One or two enlarged glands could be felt near, but there was no distinct fluctuation in the swelling itself. It did not vary with the position of the patient, it could not be diminished in size by pressure, and there was no impulse on coughing. When first examined the impression given was that of a chronic abscess of the glands in the groin; but its duration was against this; moreover, the sense of fluctuation was not clear. Then the question of fatty tumour had to be considered; the swelling resembled a fatty tumour in many ways, but it was not thought to be one from the want of distinct lobulation and the age of the patient. The duration of two years was against *nævo-lipoma*. After the patient had been in hospital for a few days the swelling appeared to become softer, and it was possible to feel that there was an attachment in the position of the saphenous opening, and although the feel was that of a fatty tumour, the texture appeared to be more loose. There was still no impulse on coughing, nor could any difference in size be produced by taxis. The opinion expressed before operation was that the tumour was probably a hernia in spite of the unusual occurrence of a femoral hernia in a young man of this age. This proved to be the case, for when a vertical incision had been made over the swelling a hernial sac was reached, but was found to contain nothing but omentum. This was reduced into the abdominal cavity, the sac dissected up and ligatured at its neck. The upper part of the incision was retracted, and the operation continued as follows:—An incision was made through the aponeurosis of the external oblique

from the external ring outwards; the lower pillar of the ring was then separated from the cord down to Poupart's ligament and the femoral ring, the neck of the sac was then freed from the ring and brought above Poupart's ligament, the ligature round its neck was cut short and the body of the sac cut away; the internal pillar of the ring and the cut aponeurosis continuous with it was brought down and sutured by means of three sutures to the fascia over the Pectineus behind the femoral canal, to Poupart's ligament on the outer side, and to Gimbernat's ligament on the inner side; the external pillar of the ring was then sutured to the internal pillar and aponeurosis which had been passed behind. A stitch was placed outside the femoral canal to approximate Poupart's ligament to the fascia of the Pectineus. The femoral ring was unusually large, admitting two fingers. The external wound was closed in the usual way. Mr. Battle said the case was an unusual one from the fact that this form of hernia was extremely rare at this age in a male; he had once had to do a radical cure for a boy, *æt.* 16, with a femoral hernia, and in both that case and the present one the cause of the hernia was probably the same, namely, want of development of Gimbernat's ligament. The hernia also, he pointed out, was unusual in its characters, as was shown by the history and by the absence of most of the signs which are relied upon for the diagnosis of any hernial protrusion. The only definite things were: the presence of a swelling in the femoral region which had apparently become softer whilst the patient had been under observation, the feeling of omentum conveyed to the fingers, and the difficulty in moving it from the femoral region. It has, he said, been noted that the femoral opening was large, and it was necessary to use some method of cure that could be relied upon to act in the case of a man who would be called upon to do hard work. The method employed fulfils the purpose, the sac is obliterated, and between the ligatured neck and the upper part of the femoral canal a shutter of strong fibrous character is interposed, and any traction which might be made on this shutter during extra exertion is transferred from the outer margin of the external ring, and aponeurosis to Poupart's ligament. The extra stitch which closes the femoral ring is possibly unnecessary but helps to consolidate the parts outside the canal.

The patient made an uninterrupted recovery.

**TWO OPERATIONS FOR EPITHELIOMA OF THE LIP IN THE SAME PATIENT.**—The same surgeon operated on a man, *æt.* about 50, for epithelioma of the upper lip and cheek on the left side. The growth was of some size, extending for about an inch and a-half inwards from the left angle of the mouth. It was typical in appearance. About an inch above it there was a raised, red portion of cheek which was very hard, and above this near the angle of the nose the skin was broken and a small malignant ulcer was forming. The glands underneath the jaw in the left side could be felt, they were evidently diseased. The mouth was small as the result of a former operation two years ago for the removal of an epithelioma of the right half of the lower lip; the scar of that operation was healthy. When Mr. Battle operated for epithelioma of the upper lip on the present occasion the operation was necessarily rather extensive; he removed the glands under the jaw in the

first place through a long incision parallel with and below the lower margin; he also divided the facial artery so as to diminish bleeding in the second stage. The tumour of the lip and cheek was removed by means of two incisions, which formed an oval, and extended about half way up the side of the nose and laid bare the upper jaw. The stitches when inserted pulled on the cheek so as to raise considerably the upper margin of the submaxillary incision, but the loose skin of the neck was brought upward, and united without tension. The operation made the mouth very small, therefore an incision was made to the right from the angle of the mouth for half to three-quarters of an inch, and the mucous membrane stitched to the skin. Mr. Battle stated that it was unusual for epithelioma to show itself in more than one place on the lips, and it was curious that this man should have allowed the growth to reach the large size it had done, because the previous operation had been a severe one simply because it was done for a large growth. The probability was thought that he had been induced by his friends to try some so-called cure. Epithelioma of the lip, he pointed out, if taken early can undoubtedly be cured.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 31, 1901.

### PROFESSOR KOCH ON BOVINE AND HUMAN TUBERCULOSIS.

THE announcement of an address on a subject so peculiarly his own by the justly celebrated German bacteriologist was an important item on the programme of the Congress on Tuberculosis, and it did not fail to attract a large and appreciative audience. The address itself, though characterised by the persuasive decision of an investigator who is dealing with facts within his own knowledge, came upon the audience like “a bolt from the blue.” Hitherto the problem of preventing the spread of pulmonary tuberculosis has been based in very great measure upon the assumption that human beings are infected to an unknown but presumably considerable extent by the ingestion of contaminated articles of food, notably the milk and flesh of diseased animals. In other words, it has all along been assumed that tuber-

culosis in man and animals is one and the same disease, and as the process of restricting the sale of infected food presents vastly less practical difficulty than that of preventing its spread from man to man, a huge superstructure of preventive measures has been erected on this basis. Judge then of the surprise which was felt when Professor Koch calmly asserted that bovine tuberculosis is distinct from human tuberculosis, that the disease cannot be transmitted from man to animals nor, inferentially, from animals to man; in fact, he regards infection by the milk and meat of tuberculous cattle and the butter made of their milk as a negligible quantity. It is impossible not to experience a shock at this bold attack on a series of conclusions which we fondly thought had been definitely established, thanks to the costly researches of two Royal Commissions fortified by independent observations from all parts of the world. The non-transmissibility of human tuberculosis to animals Professor Koch claims to have clearly demonstrated, but he is less emphatic with regard to the possibility of the transmission of bovine tuberculosis to man, simply because direct experiment could not be resorted to. It is obvious that conclusions of this far-reaching importance cannot be accepted without the closest scrutiny. The prevalence of intestinal tuberculosis among infants, presumably of alimentary origin, certainly suggests possible infection by contaminated milk; but in regard to this question, M. Koch's statistics are strikingly at variance with our own. Before discrediting the conclusions embodied in the Report of the Royal Commission, it behoves us to await further independent inquiry. In the meanwhile we must refer our readers to the address delivered by Professor McFadyean, an abstract whereof we publish elsewhere. This is virtually a reply to Professor Koch's indictment, and although it does not invalidate his conclusions it shows that there are many and weighty reasons for suspending judgment. It is hardly necessary to point out that even if the non-transmissibility of human tuberculosis to animals had been placed beyond the reach of criticism, it by no means follows that the converse is true, viz., that the tuberculosis of animals is not transmissible to human beings. It would seem that the tuberculosis is a more virulent disease in animals than in man, and it is conceivable that in passing through human beings it undergoes attenuation, to such an extent indeed as to render its retransmission to cattle difficult though not impossible. The question, so far as it relates to the amenability of human beings to infection by the germs of animal tuberculosis, will have to be worked out in the light of clinical observation, a process which presents considerable difficulty and no small degree of uncertainty. Professor Koch deserves credit for having had the courage to proclaim such heterodox views, and whatever conclusion we may ultimately come to with regard to their accuracy he will have rendered the immense service of having called attention to the vastly greater import-

ance as a factor in the dissemination of tuberculosis of man to man infection. In our anxiety to stamp out alimentary tuberculosis it may be that we were on the point of going off on a false scent, false in the sense of attaching thereto an importance in excess of its merits. This Congress will be memorable in the history of the movement in that the rudder has been shifted and we have been invited to rectify an error of direction.

#### A NATIONAL CONCERN.

THE continued destruction of our army in South Africa by enteric fever and dysentery is a subject of vital national importance. It is with the object of remedying this destruction that a Committee of hygienic experts are at present holding an inquiry in South Africa. This subject is a highly interesting one, and forms the theme of a recent publication by Dr. Leigh Canney, of London. (a) That the death-rate from these diseases in the present war has been far greater than from all other causes put together none will deny. It is apparent to any observer of the weekly casualty lists. Enteric fever and dysentery have from time immemorial been the scourges of all armies in the field, and there was no reason to expect their absence in this campaign. In fact, it was known for a long time before the outbreak of hostilities that enteric fever was endemic in South Africa. The Army Medical Department fully recognised this, and expected epidemics of it at certain periods of the year. The relationship between the Army Medical Department and the War Office is a peculiar one. In the event of any war being threatened, the Adjutant-General communicates with the Director-General of the Army Medical Service, and informs him where the war is to take place, and the strength of troops likely to be employed. It is then the duty of the Chief of the Medical Department to submit a proposal as to the medical requirements. After this proposal has been discussed by the Army Board, the Director-General submits a memorandum showing the probable diseases likely to be encountered, the kind of supplies and the kind of provisions likely to be got, and all details connected with the sanitary part of the campaign. Having done this, the Medical Department has to wait its turn and get its recommendations sanctioned by the Army Board, on which the Director-General has neither seat nor vote—a most curious anomaly! He merely acts as a spectator and rarely reaps any benefit if the campaign is a successful one, whilst he is certain to have to bear the brunt of anything which goes wrong. Dr. Leigh Canney fully recognises this state of affairs in his recent publication "Typhoid the Destroyer of Armies and its Abolition," and brings before the public *the facts* which stand in the way of any suitable prophylactic measures being adopted against these diseases in war. He attributes the lack of preventive

(a) "Typhoid, the Destroyer of Armies, and its Abolition." By H. E. Leigh Canney, M.D. Lond. Bailliere, Tindall and Cox. 1901. 1s.

measures, not to the Army Medical Department, which advised everything necessary, but to the persons who would not act upon this advice, namely, the Commander-in-Chief at the time the war broke out. Lord Wolseley's attitude towards our professional brethren in the Army is well known. In the past it has been responsible for the difficulty of filling the ranks of the R.A.M.C., and now it would seem to have led him into even graver errors of omission. In the course of his remarks Dr. Canney says: "The danger was known and calculated upon, he (the Commander-in-Chief) made no adequate provision to meet it." Such a rôle is not surprising of the man who condemned the sanitary officer as a "useless encumbrance" in time of war. We do not, however, wish to dwell upon errors which, are, we trust, over. The future, under the control and with the sympathy of, the present Commander-in-Chief is of more practical importance. The Royal Commission on South African Hospitals has suggested what Dr. Canney now suggests, and what has been recommended over and over again, namely, the appointment of "young, able, general sanitary officers of high rank from the officers of the R.A.M.C." How often has this advice been tendered to the War Office? How often has it been ignored? Now is a suitable opportunity for reform. Mr. Brodrick's "Committee on the Army Medical Service" is sitting in London at present; let it consider this among the many reforms needed. Let them select from their officers the men most qualified for these posts, and give them some stimulus for their work—extra pay, and sufficient study leave, to keep their knowledge up-to-date. Dr. Canney suggests a scheme for sterilisation of water on field service which is worthy of the closest consideration. He has devised a machine which can supply fifty men in less than twelve minutes with fifty pints of boiling water, and this water can be cooled for drinking by a special apparatus in five minutes. His boiler fitted in a case with a cooling apparatus weighs seventy pounds. Six pints of petroleum, sufficing for four pints of boiled water daily for each of the fifty men for four days, weighs seven and a half pounds. Two such machines and double the supply of petroleum can be carried by a mule and should accompany each unit of 100 men. Further, Dr. Canney advocates the formation of a "Water Corps" to take charge of this outfit and look after all water supplies. Petroleum has undoubtedly its advantages, but its inflammable nature and the consequent danger of its proximity to a waggon laden with lyddite must not be lost sight of. Indeed, it is very questionable if any of our generals in view of grass fires and stray shells would view its introduction with equanimity. The weight of the outfit is also a cause of difficulty. Each company of a regiment would require one mule, a battalion thus requiring ten mules. As two pack mules per battalion are only allowed for ammunition, and two per battalion for machine guns, it is very questionable if the military authorities would sanction the increase

which to convey apparatus entails. It will take many years of education to win over the *laissez-boire* section of our combatant officers and men, and we are afraid that the saying "Tommy will drink when he likes," will hold good for many a campaign to come. Still, we think that even our military chiefs will some day learn that if a preventable disease can destroy an army more rapidly than the strongest enemy, it is worth their while to allow steps to be taken which will make the prevention of enteric fever an accomplished fact, instead of a subject for red tape and departmental obstruction.

#### RURAL MEDICAL OFFICERSHIPS OF HEALTH.

THERE is every reason to be proud of the position taken by the United Kingdom in the practical administration of public health matters. By common consent this country has been awarded the first place among the nations with regard to that detail whereby the vital welfare of the community is so profoundly influenced. At the same time it is necessary from time to time to review the situation and to remind ourselves of the fact that a great space intervenes between present imperfections and the future sanitary millennium. One of the most obvious matters that demand attention is the inequality of standard between urban and rural sanitation. That such should be the case is not altogether surprising when we take into consideration the differences in wealth, density of population, general enlightenment, and other essential conditions that closely affect not only the public spirit but also the centralisation and decentralisation of local government. In sparsely-inhabited rural districts it is not too much to say that sanitary administration is often of the most primitive and perfunctory character. In the majority of cases the duties of the medical officer of health are entrusted to a country practitioner who receives a small and not infrequently a paltry salary in return for his services. The conditions of such an appointment are clearly not conducive to thorough and energetic action on the part of the medical officer. His duties with regard to bad housing, bad water supply, bad drainage, defective dairies, and the hundred and one details that fall within the purview of his office are no less manifold than important. By carrying them out, however, with anything like vigour and impartiality he would find himself arrayed against landowners, tenants, members of local governing bodies, in short, against the main body of his patients, high and low, throughout the district. It would be too much to expect of frail human nature to undergo an ordeal of that kind. The usual result is that the rural medical officer of health draws his salary, and as far as possible lets sanitation look after itself. The outcome of this temporising attitude is writ large in the numerous Local Government Board inquiries from time to time upon the sanitary state of this or that rural district. Many of the plague spots thus brought to light have been described in the columns of the

**MEDICAL PRESS AND CIRCULAR.** Their existence is enough to warrant a good deal of heart-searching among those public health experts who plume themselves upon the advanced preventive standards that have been attained in the United Kingdom. There can be no doubt that the Local Government Board would be able to help on reform by insisting that in all cases an adequate salary should be paid to the rural medical officer of health, and that he should have a tenure of office not less stable than that of his urban brethren. Still more, again, would be effected by bringing pressure to bear upon County Councils to appoint medical officers for their districts. By amalgamating a number of petty rural appointments it would become possible to secure the whole services of a specially qualified and well-paid man for a county. These considerations are of the utmost importance in view of the close connection that has of recent years been recognised as existing between town and county sanitation. A large proportion of the food of the urban population comes from rural districts. Again and again has the epidemic disaster of the towns been traced to the sanitary sins of the country. In spite of Professor Koch's views, the English sanitarian will continue to believe that bovine tuberculosis lies at the root of much of the human tuberculosis that decimates the inhabitants of our cities. The rigid and systematic inspection of farms and dairies is demanded in order to protect the urban population from the great scourges of tubercle, enteric fever, and scarlet fever, not to mention others. Of late years the need of close concerted action between the sanitary authorities of town and country has been widely recognised. Obviously, however, the value of such an arrangement will depend on the strength of the combining organisations. It is necessary, therefore, on this important ground as well as others already mentioned that the sanitarians of the United Kingdom should forthwith set their rural sanitary house in order.

### Notes on Current Topics.

#### Complimentary Dinner to Surgeon-General Jameson, C.B.

A COMPLIMENTARY dinner was given to Surgeon-General Jameson on Wednesday last, with Sir William Church, Bart., President of the Royal College of Physicians, in the chair, in the Grand Hall of the Hotel Cecil, at which upwards of 150 representative medical men assisted. The Chairman, in proposing the toast of "Our Guest" reviewed this distinguished officer's career from the days when he took part in repelling the Fenian raiders in Canada to his appointment to the post of Director-General of the Army Medical Department in 1896, a post which he had held during a very eventful and trying period, in respect of which every credit was due to him and to his department. Surgeon-General Jameson, in replying to the toast, dwelt upon the difficulties with which he had to contend during the strain of the war, and

pointed out that with regard to supply the medical department was only responsible for medicine and medical and surgical appliances, food and so-called medical comforts being supplied on requisition to the Army Service Corps. Consequently the blame, if any, should be apportioned to those on whom it properly fell. With respect to ambulance arrangements, he pointed out that the post of medical officer had been abolished against the advice of the medical department. Then, again, the selection of sites for hospitals in camps was the duty of the Royal Engineers or of the barrack department, but as a matter of fact the medical department had had to undertake the adaptation of buildings at a time when their hands were full of their own work. A large increase of medical transport was indispensable in future if war was to be carried out on humanitarian principles. Lastly, he remarked that the Director-General was not a member of the War Office Council or of the Army Board, so that matters concerning his department were discussed in his absence, only coming to his knowledge after considerable delay. Sir William McCormac, in proposing the toast of "The Public Medical Services," expressed regret at the fact that there was not at present a single candidate applying for admission to the Services. He thought the Army Medical Department had done its work extremely well under circumstances of considerable difficulty. They had received blame which belonged to other departments, and it was strange, he observed, that the Government had allowed Surgeon-General Jameson to leave the Army without the customary recognition given to every one of his predecessors and without one word of thanks or acknowledgment. The speeches were listened to with great attention, and as an expression of admiration and respect for the late Director-General the dinner was eminently successful.

#### Nasal Reformation.

At a recent meeting of the medical board of the Massachusetts General Hospital Dr. J. P. Clark showed a patient who had applied to him for relief in respect of a nose which sinned against her æsthetic soul in the direction of too pronounced a Roman outline. The prominent angle which characterises this variety of nasal appendage is due to the projection forward of that part of the septum, and, as shown by Dr. Goodale, this can be remedied without tampering with the skin. Dr. Clark followed his procedure, which consists in passing a pair of short curved scissors into the left nostril, one blade being made to perforate the septum just below the lower end of the prominence. Then, with the convexity of the scissors upwards, he frees the septum opposite the prominent part of the nose, following as closely as possible the contour of the nose. He next snips off the projecting piece of septum by the aid of a pair of straight scissors, and saws through the nasal bone as nearly as possible at its junction with the nasal process of the superior

maxillary bone, care being taken not to injure the skin. The process is repeated on the other nasal bone, and then a few taps on the external projection is sufficient to break down the frontal articulation. The bones can then be depressed into contact with the revised septum, and the deformity, if it is to be regarded as such, subsides. The result, judging from the photographs shown, was very satisfactory. It may be that in operations of this kind surgeons may find the means of occupying their time during the dead season if only the public can be induced to take enough interest in their personal appearance to consent to their too prominent contours being rounded off. Hitherto surgeons in this country have limited their efforts to the restoration of noses which have been eaten or blown away, and in rare instances to the ablation of redundancies of fibrous tissue in the subjects of chronic alcoholism. Purely cosmetic operations offer a much wider scope, but, so far, ladies display marked reluctance to modify the features bequeathed to them by undiscriminating sires.

#### Death from Cocaine Poisoning.

AN inquest was held last week at Cromer on the body of a young married woman who had succumbed to the effects of cocaine injected in view of a dental extraction. The assistant, an unqualified man, made three injections, equivalent to one grain of the alkaloid, and shortly after the teeth had been extracted convulsions set in, and death supervened within an hour without consciousness having been regained. It is remarkable that death should have resulted from this comparatively small quantity. According to Dr. Murrell recovery has followed the injection of as much as fourteen grains, though anything over half a grain may give rise to very unpleasant symptoms of cardiac oppression. The most unsatisfactory feature of the case is the administration of the drug by an unqualified assistant, who ran some risk of being committed for manslaughter, but the jury tempered justice with mercy by describing it as an accidental occurrence.

#### Army Hospital Accommodation in London.

DAY by day the public attention is being called to some fresh flaw in the administration of the Army Medical Department. During the past week the *Daily News* has made a fierce frontal attack upon the army hospital accommodation for the metropolis. It seems that scarlet fever has broken out among the men of the 1st Life Guards, now stationed at Knightsbridge barracks. The significance of the outbreak lies chiefly in the fact that the construction of the barracks in question is bad from a sanitary point of view, and that the building is overcrowded. There is no special army fever isolation hospital, so that the fever patients are sent to the public infectious hospitals, a proceeding which is, doubtless, most advantageous to themselves and to everyone else concerned. The fact that the barracks are not open to control

by the district local sanitary authority, however, constitutes a standing menace to the public safety. As a class, army medical officers are not, and probably never will be, sanitary experts. Why, then, should not the barracks be handed over to the district medical officer of health? It may safely be predicted that were public sanitary authorities entrusted with the supervision of military quarters the present system of housing would speedily be revolutionised. The Metropolitan Station Hospital in Rochester Row has been condemned over and over again by boards of inquiry, yet it still furnishes an object-lesson of military maladministration. The British Army, which is the most costly in the world, is provided with a wretched hospital that no civilian would tolerate for an hour. The problem before the reformer in army medical matters appears to be where to begin sweeping out the Augean stable.

#### The Government Tax on Quackery.

A WEEK or two since an enterprising tradesman was fined by the Rochdale magistrates for selling medicine in the market-place, first, without a stamp, and secondly without a license. It appears that the defendant vended some stuff called "Critchley's Indian Balm," whereby he professed to cure indigestion, at the extremely moderate price of sixpence a bottle. As to the merits of that particular preparation it is, of course, impossible to pronounce absolutely, but it may fairly be assumed that the "balm" was about as worthless as most of the cures for dyspepsia sold under cover of a quack label. Moreover, the varieties of dyspepsia are legion, and demand an infinite variety of skilful treatment, a fact that may be commended to those who pin their faith to ignorant charlatans with their "cures" for indigestion. The Rochdale prosecution, however, contains an even profounder moral. The proprietor of the balm in question, it appears, had a license to sell his precious stuff in Oldham but not in Rochdale, whence arose the police-court trouble. The position of a Government that issues a license for the sale of quack medicines is peculiar. In return for a paltry annual payment permission is granted to any quack to sell his worthless and fraudulent wares. If it be shown that such stuff is injurious to the health of His Majesty's lieges then the Government most clearly becomes accessory to a felonious act. This view of the matter may be commended to *Truth*, the only lay journal with the courage of its opinions in dealing with quack medicine vendors.

AN adjourned meeting of a number of members of the profession practising obstetrics and gynaecology was held in London on July 24th, under the presidency of Sir John Williams, at which it was unanimously resolved to establish a new journal, to be called *The British and Colonial Journal of Obstetrics and Gynaecology*, and to raise the funds required for its publication by the formation of a limited liability company.

### A "Herbalist" Sentenced to Death.

THE recent sentence to death of a "herbalist" at Hartlepool for the wilful murder of a woman by illegal operation calls for some comment. The occupation of a "herbalist" is an anomalous one, and there can be no doubt that the title is in many cases simply a cloak for nefarious practices. That the man who carries on that kind of business is often an abortionist is notorious. It would be well, therefore, for the police to keep a tight rein on all "herbalists." There are many ways in which such men might be brought to book, in spite of the deficiencies of the Medical Acts. A few well-directed prosecutions might drive away this sort of charlatan from a town before he committed the more serious offence of procuring abortion. The herbalist trade, however, at its best must be a wretched fraudulent kind of quack medical practice, and as such should be suppressed by law. What we really want is a bracing up of the Medical Acts, so that all unqualified practice could be promptly and efficiently suppressed. The present Acts are rendered inoperative for the most part simply because an offender to become liable must style himself a medical man. The simple amendment of that particular would strike a death-blow to an enormous amount of quackery now practised at the cost of life and health to the nation.

### Death from Fright (?)

ANY departure from the stereotyped formula of "weak heart" as an explanation of death under chloroform is welcome, but we question the possibility of diagnosing death from fright while under chloroform from death due to asphyxia, the usual cause of death in fatal cases of chloroform narcosis. At an inquest held a few days since at Stockport, on the body of a man who had died "before he had inhaled it in any great quantity," the convulsions were attributed to fright, and this view was endorsed by the jury. It would have been more to the point if the jury had inquired how much chloroform had been administered, by what means, and with what precautions, though in all probability they would not have been any wiser for their trouble.

### British Medical Association.

THE sixty-ninth annual meeting of the British Medical Association was opened at Cheltenham yesterday (Tuesday), under the presidency of Dr. George Bagot Ferguson, who delivered his presidential address last evening at the Princess Hall of the Ladies' College. The meeting was preceded by a special service at 11.30 o'clock at St. Matthew's Church, when the sermon was preached by the Dean of Gloucester. To-day (Wednesday) Dr. James Frederick Goodhart, F.R.C.P., is to give an address in medicine at 8 p.m. in the Princess Hall. On Thursday Sir William Thomson, C.B., M.D., Honorary Surgeon to the King in Ireland, will give an address in surgery at 2.30 p.m., after which the Stewart Prize will be presented to Dr. Patrick

Manson, F.R.S., for his researches in the pathology of tropical diseases, especially in regard to the malaria of man and to the life-history of the malarial parasite both in man and in the mosquito, and in recognition also of the stimulating influence which he has exerted for many years on the study of tropical diseases in the British Empire. The scientific work of the meeting is being conducted in thirteen sections. The first general meeting of members was held in the Princess Hall of the Ladies' College on Tuesday at 2.30 p.m., when the report of Council and the reports of committees were considered.

### The Privacy of Medical Examinations.

IT has been more or less the custom at medical examinations under the Workmen's Compensation Act for the solicitors of the parties to be present, a practice which presents obvious inconveniences, but one against which it was difficult to effectually protest. Thanks to the action of Judge Addison, of the Southwark County Court, an official pronouncement has been obtained, which will serve as a guide in future. In a case recently before him, in which the medical evidence was contradictory, the matter was referred to the Home Office referee. The solicitors wished to be present at the examination, and permission having been refused a request was made for a copy of the referee's report. This the judge also refused, and applied to the Home Office for an opinion on his ruling. We are pleased to learn that his Honour's ruling has met with the cordial approval of the Home Office, and it is now laid down that medical examinations are to be made privately, and that the referee's report, being primarily for the guidance of the Judge, is of the nature of a confidential document, though he can communicate it at his discretion. Apart from the economy of law costs which will result from this decision, it is obviously desirable that medical examiners should not be hampered by the presence of lawyers whose interference could only have for effect to add to the difficulty of making the inspection thorough, searching, and impartial.

### Plague at the Cape.

IT may be doubted whether we at home have ever properly estimated the danger of the plague at the Cape. A rigorous press censorship kept back the news of the arrival of the malady weeks after it had been announced in the Continental journals. In spite of official repression, however, information has leaked out of cases of plague in various places up country. We cannot help thinking that a policy of candour would be better calculated to maintain the confidence of the public. There has recently been a marked remission in the amount of disease at Cape Town, but that the scourge is still potent for mischief is shown by the fact that three fresh cases were notified in the last week under official report. From the beginning of the epidemic to the end of the period mentioned there have been altogether 772 cases of plague and 368 deaths

Anyone conversant with the conditions of plague must at once recognise the menace contained in that statement. The total volume of specific infection thus involved is enormous, especially in a country with such imperfect sanitary administration as the Cape. It is to be hoped that the authorities at the War Office will not allow themselves to be lulled into a false sense of security by the apparent diminution of the numbers attacked by the malady.

#### The Inwardness of the Horses' Sun-bonnet.

SOME years ago the attention of the medical profession was first drawn to the straw hats used for the purpose of protecting the heads of horses from the sun. Since that time the fashion has not only grown in popular favour but has further blossomed out into a crop of eccentric and fantastic vagaries. The original headgear made out of a plain peaked straw hat, with holes cut for the ears, has developed into hats of manifold pattern decorated with ribbons and artificial flowers, and in variously shaped contrivances slung in the air at angles more or less calculated to protect the cranium of the noble animal beneath. All this ingenuity is a good sign of the humanity that underlies the outer shell of mankind. The horse may be mercilessly whipped, or under-fed, or overworked, or tied up with bearing-reins, but at any rate here is an opportunity for showing that we do not altogether neglect his bodily comfort. As to any beneficial effect to be derived from the equine sun-bonnet it is open to question whether any additional safety is thereby conferred upon the long-suffering animal concerned. Science has shown that sunstroke is not due to heat but rather to micro-organisms. The part played by hot weather consists in providing the conditions necessary for the development of the "sunstroke" organisms. All the same it is advisable to protect the skull from the rays of the hot sun, whether tropical or otherwise, and on that ground the use of the sun-bonnet for horses may be consistently upheld. One word of caution may perhaps be added. The openings in the headgear should be so made that there is not the least friction or pressure upon the ears. Those most sensitive organs are in constant motion, and anything that restricts their free movement must prove a source of never-ending irritation to a horse, to say nothing of the actual galling that may ensue. If this fashion is not to rank among the most foolish of modern freaks it should be followed with some regard to the dictates of common sense and to the laws of physiology. In other words, it should not be allowed to become a completely feminine fashion.

#### The Interpreters of Professor Koch.

AT the combined meeting of Sections 2 and 3 of the Congress on Tuberculosis, held at the Royal Medical and Chirurgical Society, on July 24th, much diversity of opinion was expressed on the value or otherwise of the use of tuberculin. Dr. Heron gave his results, and Dr. Theodore Williams, in recounting his experience, was in direct opposition, both as

to fact and theory, to Dr. Heron. Dr. Heron's views were practically those of Professor Koch, and when the latter replied, at the end of the discussion, in the German language there was a very loudly expressed wish that his views should be then and there expounded in English to the meeting. Whether it was difficult to follow Professor Koch, or whether the gentlemen who attempted to convey his meaning to the section failed to comprehend his argument, it is difficult to decide; but it was amusing for the section, though disconcerting to the interpreters, to see Professor Koch shake his head at the various attempts made to explain his views. There was no lack of volunteers to enlighten the meeting as to what they thought Professor Koch meant, but as time was precious and the translators did not seem to find favour as regards accuracy in the eyes of Professor Koch, the chairman brought the amusing incident to a close. The amateur interpreters must be credited with firm belief in their ability to correctly translate the views of Professor Koch, for the members present indulged in remarks which were painful and frequent and free, and by no means uttered in low tones, on the respective merits of the different performers. The sections sat from half-past nine to half-past one, and the unofficial entertainment provided was much appreciated.

#### Expectation and Expectoration.

THE ceremony of inaugurating the British Congress on Tuberculosis was naturally a very serious and dignified affair, and the wonderful patience of the number of ladies who sat the decorous function right through is much to be admired. St. James's Hall, in which the ceremony of opening the Congress took place, became, on account of the weather, terribly hot, and by the end of the function many of the audience were observed to be quietly slumbering. Those who were able to keep awake were rewarded with one amusing incident; a most worthy and distinguished foreigner, of great scientific repute, was addressing the audience in English, and he spoke remarkably well, but in his excitement in delivering his peroration he expressed the hope that the Congress would come up to their expectation. Quick though he was to correct himself his audience had recognised the humour of the verbal slip, and the roar of laughter prevented the speaker from continuing his discourse for some little time.

#### Vegetarianism and Phthisis.

LORD DERBY must be congratulated on the marvellous tact with which he was able to deal with unexpected interruptions in the course of the conduct of the business of large public meetings. He presided at the final meeting of the British Congress on Tuberculosis on July 26th, and was skilfully securing the successful acceptance by the assembly of the very wordy and non-committal series of amendments which were laid before the members and delegates, when suddenly he found himself addressed by a lady whose name was understood to be Mademoiselle Vergelle, and who spoke clearly and to the point.

She addressed the meeting because, in her opinion, a great deal could be done towards stamping out tuberculosis if the medical profession were to pay greater attention to the value of prescribing a vegetable diet. Lord Derby listened with the utmost courtesy to all that the advocate of Vegetarianism had to say, and having waited for a short time to see if anyone wished to continue the theme, he pleased the audience by passing on at once to the business of the meeting, and thus succeeded in preventing any waste of time without subjecting the courageous lady to any feeling of mortification. The meeting is to be congratulated on having secured such a tactful chairman, and Lord Derby complimented on his gallantry.

#### The Liability of Sanitary Officers.

ONE of the verbose resolutions passed at the final meeting of the Congress on Tuberculosis was to the effect that sanitary officers should be encouraged in their efforts to prevent the increase of tuberculosis. Some gentleman whose name did not transpire, speaking from the midst of the crowded audience, very pertinently suggested that the meeting should pass an expression of opinion that the sanitary officers should be freed from their present liability in respect to their efforts to prevent the sale of tuberculous milk. The speaker was greeted with loud cries of dissent, which he very successfully met by showing the necessity of doing what he advised, and gave as an example the fact that a Sanitary Officer at Warwick had been subjected to legal proceedings for slander because he had done his duty in his official capacity for the protection of the public. Perhaps the fact that the meeting was detained from attending a popular water-picnic at Richmond may have accounted for the cold welcome accorded to the very reasonable proposal. The matter, however, is of some importance, and must not be allowed to drop.

#### The Plague.

THE reappearance of the plague in Honolulu in spite of the very comprehensive precautions taken against the epidemic is, to say the least of it, embarrassing, but the obstinacy with which the infection continues to make itself manifest in Cape Town, not only among the coloured races, but equally so among the whites, together with the reports concerning the seventh recrudescence of the plague in Hong Kong, renders a consideration of the present outlook a far from cheerful one. There is not much consolation in the information that when once a town has been infected recurrences must be expected, and the worst of it is, judging from Hong Kong, the attacks by no means seem to decrease in virulence as they increase in number. As far as can be judged from the facts to hand, this last outbreak in Hong Kong threatens to be the most serious calamity that that district has as yet suffered. For anyone to accept as proved the assertion that modern scientific methods are perfectly able to cope with plague requires either very robust faith or a large measure of obstinate prejudice.

#### Excessive Cough in Phthisis.

THE treatment of excessive cough in a tuberculous patient requires much judgment. A certain amount of cough is undoubtedly in a large number of cases indispensable and has a salutary influence. The treatment of this symptom was discussed by Dr. Huggard, of Davos Platz, before the Congress on Tuberculosis, and as he very well put it, the problem is to secure the removal of the pulmonary and bronchial secretion with the least amount of violent exertion or fatigue to the patient. The difficulty is that sometimes the secretions are very abundant and sometimes too scanty. The balsams and the terebinthines diminish secretion and apomorphine in small doses loosens the secretions. The recently introduced morphine derivatives, heroin and dionin diminish cough and expectoration, are devoid of constipating effects, and do not disturb the digestion. The indication appears to be that Dr. Huggard's views are in accord with others, and in a clinical lecture lately delivered at St. Bartholomew's Hospital Sir Lauder Brunton mentioned heroin as a useful therapeutic agent for cough, under the circumstances described.

#### The Diagnosis of Tuberculosis.

A MEANS of diagnosis in pulmonary tuberculosis is found in the attentive study by means of the radioscope of the function of the diaphragm and inspiratory muscles. If one examines a patient apparently in a good state of health, or simply affected by weakness, and the movements of the lungs are studied together with the degree of clearness of the lungs, and especially the action of the diaphragm, a diagnosis may be arrived at in the pre-tuberculous period. The opinion is formed by noticing anomalies in the synchronism and amplitude of movement of the two halves of the diaphragm in their rise and fall or in their curvature, and it is possible, in the absence of any other sign, to give a diagnosis of a predisposition to, or commencement of, tuberculosis, unless an evident cause for these anomalies can be discovered. This subject has been exhaustively treated by Dr. Bonnet Leon, of Paris, and he has communicated his views to the British Congress on Tuberculosis.

#### The Next International Congress of Medicine.

THE fourteenth International Congress of Medicine will be held at Madrid from the 23rd to the 30th April, 1903, under the patronage of King Alphonso XIII. and the Queen Regent. The subscription is thirty pesetas (equivalent to twenty-four shillings). Ladies accompanying members will be able to obtain the privileges of members, i.e., reductions on the Spanish railways, &c., on payment of twelve pesetas, or ten shillings apiece. The National Committee for Great Britain and Ireland remains the same as at the Paris Congress, Sir William MacCormac, Bart., K.C.B., K.C.V.O., being the President. The honorary secretaries are Dr. Percival Horton-Smith, of 15 Upper Brook Street,

Grosvenor Square, W., and Mr. D'Arcy Power, F.R.C.S.Eng., of 10A Chandos Street, Cavendish Square, London, W.

#### Compensation for Condemned Meat.

THE members of the Veterinary Section of the Congress on Tuberculosis were very much in evidence at the fifth general meeting of the Congress. Every seat in the Queen's Hall, where the meeting was held, had placed upon it a copy of the resolutions submitted to the Veterinary Section in regard to the confiscation and destruction of condemned meat. Mr. J. Bowen Jones tried without avail to persuade the Chairman to allow these resolutions to be submitted to the meeting, but Lord Derby said he was unable to do so because they contained so much matter of an argumentative nature. Mr. Bowen Jones was assured that the resolutions would be considered by the proper authorities, and like a wise man, seeing it was hopeless to press the matter further at that moment, he acquiesced in the inevitable.

#### The Sale of Cocaine.

THE suicide of two young women in London by taking cocaine has served the useful purpose of directing public attention to the ease with which comparatively large quantities of this highly poisonous drug can be obtained. There is reason to fear that the practice of using the alkaloid as an intoxicant is on the increase. In reply to a question in Parliament by Mr. Macdonald, it was stated that a committee of the Privy Council has been appointed to consider the first schedule of the Poisons Act (1868), and that the expediency of placing cocaine in that list will be referred to it.

#### Liability for Domestic Servants.

IN an action brought by Dr. Williams, of North Walsham, Norfolk, against a servant for medical attendance the claim was opposed on the ground that the girl's master had sent for the doctor, and not the patient herself, and on that ground the judge gave judgment for the defendant. The jurisprudence in such matters is now pretty well established, and it would be well in every instance for the practitioner who has been called to a servant to have a clear understanding as to who is going to be responsible for the fees.

WE are requested to call the attention of those of our readers who purpose availing themselves of the "tour of instruction" organised by Dr. Carron de la Carrière through the watering-places of Southern France, to the fact that all applications must reach him at his address, No. 2, Rue Lincoln, Paris, before August 15th. No more favourable opportunity could be offered for visiting these picturesque sites and of becoming acquainted with the therapeutical value of their springs. The cost of the round trip, including travelling and hotel expenses, carriage journeys, &c., is 300 francs (£12).

AN inquest was held on the 22nd inst., at Birmingham, on the body of a man who had succumbed to chronic brass dust poisoning, and the coroner intimated his intention of representing to the Home Office the desirability of instituting an inquiry into the subject. We have no knowledge of specific intoxication as the result of inhaling brass dust, and it is probable that the deleterious effects with which it is credited are in reality due to the irritating effects of the dust, as such, on the air passages.

Two patients supposed to be suffering from plague were landed last week at Plymouth from the Orient liner *Ormuz*, and a number of passengers were vaccinated as a precautionary measure, all the crew having undergone this prophylactic measure during the voyage. Bacteriological examination, however, did not confirm the suspicions, and all restrictions have now been removed.

THE death is announced of Dr. Edward S. Morley, J.P., of Blackburn, at the age of 70. Dr. Morley in his younger days was an enthusiastic athlete, and took an active part in the local organisations having in view the development of the various sports, but he was also a much esteemed physician, and his death has excited widespread regret.

#### PERSONAL.

DR. E. J. MACLEAN has been appointed Gynæcologist to the Cardiff Infirmary out of six candidates.

DR. JOHN JONES, who recently returned from South Africa, has been appointed Medical Officer to the Mond Nickel Works, Clydach.

MR. R. WHITESIDE STATHAM, M.R.C.S., has been appointed Deputy-Coroner for North Somerset, *vice* Dr. J. Wallace, who has resigned.

THE Fellowship of the Royal College of Physicians, London, was bestowed on Dr. W. J. Tyson, of Folkestone, whose Membership is dated 1889.

IT appears that Dr. Isambard Owen has not seen his way to accept the offer of the post of Principal of the Cardiff University College which was offered to him.

MISS AGNES REYMNER SINCLAIR, M.B., Ch.B. Glasg., of Clarenceville, Longsight, Manchester, has been appointed Resident Medical Officer to the Carlisle Dispensary.

THE Colonial Office has notified that Dr. E. Bowmaker, of Sunderland (an old subscriber and contributor to this journal), who was in the Ashantee Expeditionary Force, died of malarial fever on July 6th at Parmu, Gold Coast Interior.

PROFESSOR ROBERT KOCH was entertained at dinner on Wednesday evening last at the Hôtel Métropole by the Royal Institute of Public Health, when he was presented with the Harben Gold Medal for 1900 and the Honorary Fellowship of the Institution.

THE "Baly Gold Medal," which is presented every alternate year by the Royal College of Physicians of London for special distinction in the science of physio-

logy, has been this year awarded to Dr. F. W. Pavy, F.R.C.P., F.R.S., consulting physician to Guy's Hospital.

THE Council of King's College, London, have elected Dr. R. Tanner Hewlett, of the Jenner Institute of Preventive Medicine, to the Professorship of General Pathology and Bacteriology; and Dr. St. Clair Thomson to be Assistant Physician for Diseases of the Throat.

DR. A. DAVIDSON, late Senior Assistant Medical Officer at the Dorset County Asylum, on his resigning that appointment to enter the Colonial Medical Service, has been presented by the medical officers and staff with a valuable tea service in silver in recognition of his "zealous work and kind attention."

DR. NORMAN MOORE has been selected by the Royal College of Physicians, London, to deliver the Harveian oration on St. Luke's Day, October 18th, and Dr. Judson Bury the Bradshaw Lecture in November. Dr. G. F. Still has been appointed Goulstonian Lecturer, Dr. F. T. Roberts Lumleian Lecturer for 1902, and Dr. C. E. Beevor Croonian Lecturer for 1903, to the same college.

DR. S. WEIR MITCHELL, it is announced, has just returned to the States from a trip around the world. Evidently the doctor has the reputation of being a worker, for a newspaper asserts that six long novels, forty-nine sonnets, 103 quatrains and several other poems, not to mention four books of sketches, a treatise on nervous diseases, fifteen or twenty short stories, were dashed off by him at odd moments during his trip. All these precious works, we are informed, are now in the possession of Richard Watson Gilder, who has hired eight detectives to watch the stuff.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

#### THE PROPOSED NEW JOURNAL OF OBSTETRICS AND GYNÆCOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In one of your "Leading Articles" in to-day's issue you draw attention to a proposal to start another *Journal of Obstetrics and Gynecology*, and as there is no advertisement or public announcement of the meeting to be held to-day, I suppose it is more or less of a private concern. Now we have had some experience of a similar effort in *The Obstetrical Journal*, which ran for eight years (1873-1800) and then expired. Nearly all the gynæcological societies in this country issue Proceedings or Transactions, in the main limited to reports of their own work, but we have already the experience of a journal, *The British Gynecological Journal*, which covers exactly the ground that is proposed to be included in the new journal, and has been in existence sixteen years. This journal is not only British, but it is cosmopolitan, and contains not only the Transactions of the British Gynecological Society, but also reports of the various gynæcological societies of the Empire, together with material from foreign countries. I do not see, therefore, where is the need or room for another journal on identical lines, nor what prospect it has of a great success, inasmuch as no private issue is likely to carry the weight or prestige that attaches to a society that has done such good work, or has so world-wide a reputation as the British Gynecological Society. Any new journal on these lines will be run mainly in opposition to the *British Gynecological Journal*, and it will require to be some-

thing especially good to have much chance of success against a journal that has run into sixteen volumes. Perhaps one devoted exclusively to obstetrics might do better.

I am, Sir, yours truly,  
HETWOOD SMITH.

Harley Street, W., July 24th, 1901.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Though there are many points raised in your leader referring to the proposed journal, there is but one that I desire through your columns to comment upon. Most emphatically the proposed journal will not be representative "of the entire obstetrical and gynæcological world of Great Britain and Ireland." Already a large number of prominent obstetricians and gynæcologists, in the metropolis alone, feel that they have been deliberately excluded from all participation in the movement. A meeting, to which they were not invited, was summoned by invitation to consider the matter, and its proceedings were limited to a favoured few. Further, it is an open secret that this journal has been conceived and taken in hand mainly by those who are openly and avowedly hostile to the British Gynecological Society and its *Journal*. Whether under these circumstances the promoters of this one-sided undertaking will succeed in creating "a universal journal" is a point which time will prove. One thing is certain—that it never will be, in the truest sense, "representative of British obstetrics and gynæcology."

I am, Sir, yours truly,

A LONDON OBSTETRICIAN AND GYNÆCOLOGIST.

[We can only repeat what we have already said. In our opinion there is room for an "imperial" journal of obstetrics and gynæcology. The more truly imperial the new journal is, the less it will interfere with the interests of individual British societies. If, as our correspondents say, the meeting of last Wednesday was "more or less of a private concern," we fear it does not augur well for the future success of the proposed journal. Who is responsible for the assumed privacy? —Ed.]

#### UNDESIRABLE PROSECUTIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With regard to your comments (*MEDICAL PRESS AND CIRCULAR*, July 24th) on the "abortive proceedings" against Dr. H. Whitmore instituted by the Medical Officer of Health for Camberwell, that gentleman no doubt according to his lights performed his duty, or at least what he thought such. It should be remembered, however, that the law has forced upon the medical profession the exceedingly delicate and difficult task of notification, hence very strong evidence indeed should be forthcoming ere the law is set into motion against any practitioner. Speaking generally of notification, medical officers of health may take it that the tendency nowadays is to notify precipitately; at least it is certain that innumerable doubtful cases are recorded and sent away at enormous public expense that would rapidly recover under the most simple treatment if the diagnosis were only delayed for a day or two, and this is proved by the fact that so many turn out futile.

I am, Sir, yours truly,

CLEMENT H. SEES.

130, Queen's Road, Peckham, S.E., July 24th, 1901.

#### FEMORAL CYSTOCELE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As femoral cystocele is very uncommon, I copy the following from the *Am. Journal of Surgery and Gynecology*:—A woman with a lump protruding from the left femoral ring, exquisitely sensitive, the size of a small hen's egg, hard, and somewhat nodular, came under observation. There was no fluctuation, no impulse on coughing, no difference in size on the woman taking the upright position, no history of constipation, and no pain during the action of the bowels.

On the operation table the lump was exposed by dissecting up a small circular flap. The operator considered that he had to deal with an omental hernia, or, perhaps, an ovarian one. After removing the fatty tissue, together with the adhesions that had formed round the sac, it was evident that the mass did not contain an ovary, but resembled a thickened piece of omentum. A snip of the piece was made for microscopic examination, and the issue of some clear fluid told that a cyst of some sort had been opened, probably the urinary bladder. The diagnosis was confirmed by the passing of a sound through a very small incision. The instrument was distinctly felt in the bladder. The opening was sutured and the bladder returned to the abdominal cavity. The patient made a good recovery.

I am, Sir, yours truly,  
Dublin, July 27th. GEORGE FOX.

#### THE ANDERSON FUND.

THE Committee formed to appeal for aid on behalf of the widow and two sons of Mr. R. B. Anderson, F.R.C.S. (see MEDICAL PRESS AND CIRCULAR, July 10th, pp. 49-50), beg to gratefully announce the following list of subscriptions to July 26th, amounting in all to £52 10s. :-

	£	s.	d.
The Earl of Stamford (Chairman) ...	10	0	0
Timothy Holmes, Esq., F.R.C.S. (Hon. Treasurer) ...	5	0	0
H. E. Juler, Esq., F.R.C.S. ...	2	2	0
Dr. Higham Hill ...	1	1	0
Dr. Lorimer Hart ...	1	1	0
Dr. Alfred Cox ...	1	1	0
Dr. Wheeler O'Bryan ...	0	10	6
Dr. Milner Brown ...	0	10	6
Walter Monnington, Esq. (Hon. Sec.) ...	1	1	0
Lord Lister ...	10	0	0
Dr. Herbert Owen ...	1	1	0
Dr. Duka ...	1	1	0
Dr. W. Domett Stone ...	1	1	0
Dr. John Brown ...	0	10	0
A Friend ...	1	0	0
Thomas Smith, Esq. ...	5	0	0
Sir R. M. Craven ...	1	1	0
E. E. Llewellyn, Esq. ...	1	1	0
J. Granville Hockridge, Esq. ...	1	1	0
Dr. C. Crawford ...	1	1	0
J. H. Waddington, Esq. ...	0	10	6
W. Smith, Esq. ...	0	10	6
Dr. C. Coates ...	2	2	0
Dr. G. F. Blandford ...	3	3	0

Total ... £52 10 0

THE EARL OF STAMFORD, Chairman.  
TIMOTHY HOLMES, Esq., F.R.C.S.,  
Hon. Treasurer.

WALTER MONNINGTON, Esq., 7, Fig  
Tree Court, Temple, E.C., Hon. Sec.

Donations for "the late R. B. Anderson Fund" should be sent and made payable to *The Manager, Union Bank of London, Chancery Lane, London.*

#### NOMENCLATURE OF DIARRHOEAL DISEASES.

THE Registrar-General for Ireland has issued the following circular letter to the medical profession in Ireland:—

General Register Office,  
Charlemont House, Rutland Square,  
Dublin, July 19th, 1901.

GENTLEMEN,—I beg to bring under your notice the fact that the Diarrhoea Nomenclature Committee of the Royal College of Physicians, London, at their meeting held on November 20th, 1899, recommended the College to authorise the use of the term "epidemic enteritis" (or, if preferred by the practitioner, "zymotic enteritis") as a synonym for epidemic diarrhoea ("Nomenclature of Diseases," p. 9, ed. 1896) and further recommended the entire disuse as synonyms of epidemic diarrhoea, in medical certificates of death, of such terms as "gastro-enteritis," "muco-enteritis," or "gastric catarrh." This recommendation was submitted

to the Royal College of Physicians, London, and unanimously adopted at a meeting of the Fellows held on January 25th, 1900.

I had the honour of bringing the matter under the notice of the Royal College of Physicians, Ireland, who have endorsed the opinion of the London college. May I ask the favour of your kind co-operation in carrying out the views of the heads of the medical profession.

I am, Sir, yours truly,  
R. E. MATHESON, Registrar-General.

#### Obituary.

SURGEON-MAJOR FREDERICK ROBINSON,  
M.D., F.R.C.P.

THE death is announced of Dr. Robinson, at Eastbourne, an old and much respected member of the Army Medical Service (retired). He entered it in 1847 as assistant-surgeon in the 74th Foot, in which regiment he continued until his transfer to the Scots Fusilier Guards in 1852. He became battalion surgeon in the year 1857, and surgeon-major of the battalion in 1867. Dr. Robinson accompanied the Scots Fusilier Guards to the Crimea in 1854 as senior assistant-surgeon, and served uninterruptedly with the battalion until the termination of the war. During a great part of the time he was in medical charge of the battalion. He was present at the Battles of the Alma, Balaclava, and Inkerman, and at the siege and fall of Sevastopol, and the sortie of October 26th, and had the British medal with all the clasps for these engagements, in addition to the Medjidieh and Turkish medals. For distinguished conduct in the field at the Battle of the Alma he was recommended for the Victoria Cross by Colonel Walker and was personally complimented for his conduct during the campaign, on the field at Inkerman by Lord Raglan and by the Duke of Cambridge after the Battle of the Alma.

MR. J. A. RIGGE, M.R.C.S., L.R.C.P., OF HENLEY.

THE deceased, who had been in failing health for some time past, died of pneumonia a few days ago at the early age of 41. He was held in very high esteem by all classes in the town and neighbourhood, and his death is much deplored. He was an enthusiastic Volunteer, and also served on the Town Council for three years. He had been for some years the medical officer of the Henley Workhouse, and was also connected with the Hearts of Oak Benefit Society, and his kindness and courtesy made him a very popular officer. The funeral took place at Bix churchyard on Wednesday afternoon, amid every token of respect.

#### Medical News.

##### Medical Gold Medallists.

THE results of the July Intermediate Examination in Medicine at the University of London were published on the 23rd inst., and the following are the students to whom medals have been awarded:—

For Anatomy: Ernest Edgar Maples, St. Bartholomew's (gold medal), and William Gordon Taylor, Middlesex (medal and exhibition). Seymour Gilbert Barling, Birmingham University, is marked "deserving of medal."

For Physiology and Histology: George Hall, University College (medal and exhibition), and Thomas de Smith (Cambridge University and London Hospital (gold medal)).

For Materia Medica and Pharmaceutical Chemistry: Arthur Campbell Stark, Westminster (medal and exhibition).

##### The Dublin Death Rate.

It is with unfeigned pleasure that we note a fall in the Dublin death-rate, which is a shade under 20 deaths per 1,000. Indeed, the present weather seems to have generally lowered the death-rate throughout Europe and America, the rates being: London, 16½ per 1,000; Glasgow, 18½; Paris, 17½; Amsterdam, 11½; Berlin, 16½; New York, 17½; Venice, 11½; Dublin,

1902. Thirty-seven of the persons whose deaths were registered during the week were under five years of age, twenty-four being infants under one year, of whom five were under one month old. It would be interesting to know how many of these little ones were nursed children, and how many were insured.

#### Royal Appointments.

Messrs. CANTRELL and COCHRANE ask us to announce that they have been honoured by the appointment under special warrant of purveyors of mineral waters to His Majesty the King. The waters supplied by these manufacturers are so universally known and appreciated that they have gained as many as thirty-two gold and prize medals. We recently put two or three of these waters under laboratory tests, and found they responded to the most searching investigation for purity.

#### Royal College of Physicians, London.

At the quarterly *comitia* of the College on Thursday last the following Fellows were elected officers of the College for the ensuing year:—Censors, Thomas Tillyer Whipham, M.D., Sir Dyce Duckworth, LL.D., M.D., Thomas Henry Green, M.D., George Vivian Poore, M.D.; treasurer, Sir Dyce Duckworth, M.D.; Emeritus registrar, Sir Henry Pitman, M.D.; registrar, Edward Liveing, M.D.; Harveian librarian, Joseph Frank Payne, M.D.; library committee, Samuel Gee, M.D., J. Wickham Legg, M.D., Norman Moore, M.D., William Henry Allohin, M.D.; curators of the museum, W. Howship Dickinson, M.D., H. Charlton Bastian, M.D., William Cayley, M.D., John Abercrombie, M.D.; finance committee, T. Tillyer Whipham, M.D., A. Lewis Galabin, M.D., and Stephen Mackenzie, M.D. The examiners for the ensuing collegiate year were elected at the same meeting.

The following candidates having passed the required examination, were admitted members of the college:—Thomas Bushby, M.B.Edin., Univ. Coll., Liverpool; Arthur H. W. Clemow, M.D.Edin., Univ. Coll., Liverpool, and Leipzig; John C. M. Given, M.D.Lond., Liverpool Royal Infirmary, Univ. Coll., London, and Vienna; Thomas W. Griffith, M.D.Aberdeen; Arthur D. Heath, M.D.Lond., L.R.C.P., and M.R.C.S., Univ. Coll., London; Thomas McCrae, M.B.Toronto, L.R.C.P., and M.R.C.S., Toronto and Göttingen; Frederick C. Moore, M.D.Vict., Owens Coll., Manchester; Harold D. Singer, M.D.Lond., L.R.C.P., and M.R.C.S., St. Thomas's.

#### The College of Preceptors.

ACCORDING to the report just issued the number of candidates for the professional preliminary examination in March last was 172, a marked increase on the figure for the previous year.

#### Leprosy in Russia.

THE measures taken to stamp out leprosy in Russia have not, so far, been attended by much success. In Lithuania, for instance, there are 609 cases under medical supervision, and there are 201 in Courland, 124 in Astrachan and 121 in the Kuban district. Last year a marked increase is stated to have taken place in the Caucasus, Central Asia, and East Siberia. In addition to the official cases there is every reason to apprehend that the disease exists in many other districts, and steps are being taken to investigate its prevalence.

#### Small-pox at Child's Hill.

THERE have been ten cases of small-pox in all at Child's Hill, the disease having been imported from Port Said. The sufferers were promptly isolated in an open-air camp, and the outbreak is now believed to be at an end, although a number of suspects are still under observation.

#### Metropolitan Asylums' Board.

DURING 1900 the numbers of patients suffering from fever, diphtheria, small-pox, and "other diseases," admitted into the hospitals of the Board were as follows:—Scarlet fever, 10,343; diphtheria, 7,873; enteric fever, 1,728; typhus, 4; small-pox, 66; and other diseases (exclusive of the non-small-pox cases detained at South Wharf or sent home at once), 1,707. The mortality per cent. was as follows:—Scarlet fever, 2.97; diphtheria, 12.27; enteric fever, 14.09; typhus, 22.23; small-pox, 4.35; and other diseases (exclusive of the

non-small-pox cases), 9.90. The bulk of the 66 cases of small-pox owed their infection to persons who themselves had contracted the disease abroad or in the provinces, and were taken ill soon after their arrival in London. During the financial year ended at Michaelmas, 1900, the managers spent £832,466, an increase of £65,682 over the preceding year.

#### Typhoid in South Africa.

IN reply to a question by Sir Walter Foster, M.P., it was stated that from returns received since June 25th the deaths for the four weeks ending April 26th are now given as 194. For the five weeks ending May 31st the admissions were 2,300 and the deaths 326.

#### More Officers for Volunteer Medical Staff Corps.

IT has been decided, in order that each Division or Company of the Volunteer Medical Staff Corps may have on its establishment a sufficient number of officers to supply the full quota on mobilisation, that additional Lieutenants shall be appointed, and officers so appointed will be granted outfit allowance.

## Pass Lists.

#### Royal College of Physicians and Royal College of Surgeons Ireland.

THE following candidates have passed the Second Professional Examination:—

(a) In all subjects.—J. Grace.  
(b) Completed examination.—P. Donnellon, A. H. B. Duncan, H. B. Evans, D. Gillies, B. D. Gibson, M. Hurley, L. F. Kelly, T. Keogh, A. C. Lewis, F. J. Moore, J. O'Doherty, J. P. O'Donnell, D. J. O'C. Kelly, P. P. Ryan.

The following have passed the Second Professional and Third Professional Examinations:—

#### SECOND PROFESSIONAL, PART II.

(a) All subjects.—Honours: M. J. Ryan. Pass: C. P. O'B. Butler, E. G. Griffin, L. B. Hanbury, Jas. Hayes, R. A. Murphy, L. P. Stokes.  
(b) Completed examination.—H. E. F. Hastings, J. R. H. Macmanus, V. H. MacSwiney.

#### THIRD PROFESSIONAL.

(a) All subjects.—Miss L. N. Alexander, J. E. Brereton, A. Charles, T. A. Dillon, Jas. Dwyer, C. Foley, Miss H. A. Hall, W. B. A. Moore, C. E. O'Keefe, P. W. Power, C. Waters.  
(b) Completed examination.—Miss M. E. Bridgford, S. Brown, J. Cuffe, Miss H. A. Driver, G. Lacy, J. J. McInerney, S. B. M'Cauleland, O. F. M. Ormsby, W. Scott, G. J. Sexton, S. A. Tucker, G. B. Wilkinson.

The following candidates have passed the final examination:—

(a) All subjects:  
1. Honours in order of Merit: P. I. Hanafin, Edmund Glenny, Miss M. J. Shire, A. H. B. Hartford.  
2. Pass; alphabetically.—H. L. A. Barry, J. P. Byrne, F. J. Cahill, M. J. Johnston, J. F. L. Keegan, I. M. S. Lewis, J. Loughrey, D. J. O'Reilly, John White.  
(b) Completed the Examination.—A. J. Connolly, P. L. Crosbie, C. H. Felvey, J. S. Lane, M. E. Lynch, R. F. MacMahon.

#### University of Aberdeen.

At the Graduation Ceremony on Wednesday last, July 24th, the following Degrees in Medicine were conferred:—

#### DEGREE OF DOCTOR OF MEDICINE (M.D.).

John Baker, M.B., C.M.; William John Byres, M.A., M.B., C.M.; Clarence I. Ellis, M.B., C.M.; Douglas Vercoe Haig, M.B., C.M.; James Selkirk Laing, M.B., C.M.; Harry Oliphant Nicholson, M.B., C.M. (New Regulations); James Porter, M.A., M.B., C.M., B.N.; James Wallace, M.A., M.B., C.M.

The Thesis of Mr. H. O. Nicholson was awarded "Highest Honours," the Thesis of Mr. J. S. Laing was awarded "Honours," and the Theses of Messrs. John Baker and Douglas V. Haig were awarded "Commendation."

The Lord Rector's prize for the best Thesis for M.D. of the year has been awarded to Mr. H. O. Nicholson.

## Notices to Correspondents, Short Letters, &c.

**✉ CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

**READING CASES.**—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of **THE MEDICAL PRESS AND CIRCULAR**, may now be had at the office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

### KNOWLEDGE AND WISDOM.

**THE** keen comment of Tennyson's when he said, "Knowledge comes, but wisdom lingers," indicates the difference between the two, a difference never better expressed than in the well-known lines of Cowper:

"Knowledge and wisdom, far from being one,  
Have oftentimes no connection. Knowledge dwells  
In heads replete with thoughts of other men;  
Wisdom in minds attentive to their own.  
Knowledge is proud that he has learned so much;  
Wisdom is humble that he knows no more."

In a recent number of the *Journal of the American Medical Association* the first item in the index is as follows: "Poverty and Pregnancy: Their Cause, Prevention and Cure. N. S. Davis, M.D., Chicago." A glance at the article shows the printer's evil genius has been "at it again." Pregnancy should read "degeneracy." The peccant genius must have been very bad that day!

**PURGATIVES.**—Salines operate in three or four hours; croton oil in one or two hours; jalap, gamboge and senna in three or four hours; rhubarb and castor oil in from four to six hours; aloes and mandrake in from ten to fourteen hours. Some pills in two or three years.

### SOME MISTAKEN IMPRESSIONS IN REGARD TO GENITO-URINARY TROUBLES.

**THE** special mistakes noticed by Dowd are: the belief in the frequency of cystitis due to gonorrhoea, the frequency of vaginitis, the recognition of albuminuria and casts as always indicating nephritis, while they occur frequently during urethral inflammation with no other disease, and the common notion of the greater seriousness of syphilis as compared with gonorrhoea; he also mentions the common belief that twisting or screw-like formation of urination as it emerges is indicative of stricture, which is not the case.—N. Y. *Medical Record*.

**A QUEER VERDICT.**—A despatch from St. Louis to *The New York Times* says that the head of a man, wrapped in an old coat, was found recently in East St. Louis, and when the coroner held an inquest over it a verdict of suicide was returned. We fancy we have seen this story before, or something very analogous thereto.

**DR. MONDE.**—Thyroid extract has been employed with success in some recorded cases of alopecia areata, but it has failed in the hands of others. It is probable that under this designation are included more than one variety of localised baldness, and in any event the constitution of the individual sufferer is a factor not to be lost sight of.

**BRIXTON.**—The charge is a fair one under the exceptional circumstance.

**EDINBURGH STUDENT.**—1. We understand a revised edition is in the press. 2. A question we are unable to answer; write to the publishers.

**MR. F. DENMAN.**—The surgeon named died about two years since. We have no copies of the number containing the obituary notice left. You will find bound copies for reference in your college.

## Appointments.

- ALLEN, W. T. D., M.B., B.Ch., R.U.I.,** Medical Officer for the 4th District of the Parish of Liverpool, vice S. Caldwell, M.B.C.S., resigned.
- COLLISON, HAROLD, M.B.Lond., M.B.C.S., L.R.C.P.,** Resident Casualty Officer to the General Infirmary, Leeds.
- CRAWFORD, E. E., M.B.C.S., L.R.C.P.,** Resident Obstetric Officer to the General Infirmary, Leeds.
- FLEMING, A. D., M.B., M.S. Edin.,** Certifying Surgeon under the Factory Acts for the Kelse District of the County of Roxburgh.
- FOWLER, H. W., M.B. Edin.,** Assistant Medical Electrician to the Royal Infirmary, Edinburgh.
- NASH, J. T. C., M.D. Edin., D.P.H. Cantab.,** Medical Officer of Health for the Borough of Southend-on-Sea.
- ORFORD, T. C., M.B.C.S., L.R.C.P.,** Resident Medical Officer to the Salford Union Infirmary.

**BORIE, GEO., M.B., M.Ch. Edin.,** Senior Assistant Medical Officer to the Dorset County Asylum, Dorchester.

**BUTHERFORD, R. A., L.R.C.P., L.R.C.S. Edin.,** Certifying Surgeon under the Factory Acts for the Kinlough Dispensary District of the Ballyshannon Union.

**SPARKS, J. P., M.D. Durh.,** Medical Officer of Health of Whitley and Monkseaton Urban Sanitary Districts.

**STEVENS, EDGAR, M.D. Aberd.,** Demonstrator in Ophthalmology at University College, Liverpool.

**STREETEN, F. E., L.R.C.P. Edin., M.R.C.S. Eng.,** Medical Officer of Health of Swindon Urban Sanitary District.

**TURNER, D. F. D., M.D. Edin.,** Medical Electrician to the Royal Infirmary, Edinburgh.

**WIGHAM, J. H., L.R.C.P. Edin., L.R.C.S. Edin., I.F.P.S.G.,** Medical Officer of Health of South Molton Municipal Borough.

**WILKINS, A. G., M.B., Ch B.,** Resident Medical Officer to the Salford Union Infirmary.

**WILKINSON, J. HOWARD, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., Oxon.,** an Honorary Surgeon to the Guest Hospital, Dudley.

## Vacancies.

**Devon County Asylum, Exminster, near Exeter.**—Third Assistant Medical Officer. Salary £125, rising to £150, with board, lodging, &c. Applications to the Medical Superintendent.

**London Hospital, Whitechapel, E.**—Assistant Director of the Pathological Institute. Salary £200 per annum.

**North Wales Counties Lunatic Asylum, Denbigh.**—Second Assistant Medical Officer. £120 per annum, increasing to £160, with board, residence, and washing.

**Nottingham General Dispensary.**—Assistant Resident Surgeon, unmarried. Salary £160 per annum, increasing £10 every year, with furnished apartments, attendance, light, and fuel.

**Oxford, Combined Rural and Urban District Councils of.**—Medical Officer of Health. Salary £750 per annum.

**Royal Sea-Bathing Hospital, Margate.**—Two Resident Surgeons, a Senior and Junior. Salary £120 and £80 per annum respectively, with board and residence.

**Rubery Hill Asylum, Barnet Green, Worcestershire.**—Junior Assistant Medical Officer. Salary £130 per annum, with board, furnished apartments, &c.

**Rural District Council of Bishop Auckland.**—Medical Officer of Health for the Rural District. Salary £350 per annum. Whole time to be devoted to the office. Applications to the Clerk of the Council, Bishop Auckland.

**St. Matthew, Bethnal Green Infirmary, Cambridge Road, N.E.**—First Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and laundry.

**Somerset and Bath Lunatic Asylum, Wells, Somerset.**—Medical Superintendent. Salary £600 per annum, with furnished house and allowances.

**University of Sydney, New South Wales.**—Professor of Pathology. Salary £900 per annum. Pension £400 per annum after twenty years' service. £100 allowed for passage. Further particulars of the Agent-General for New South Wales, 9, Victoria Street, London, S.W.

**Whitehaven and West Cumberland Infirmary.**—House Surgeon. Salary £120 per year, and £30 per year for Dispensing, with furnished apartments and attendance.

## Births.

**GRUBER.**—On July 23rd, at Neuenahr, Germany, the wife of Karl Grube, M.D., L.S.A. Lond., of a son.

**MACLIE.**—On July 24th, at Wellington, Shropshire, the wife of George MacLie, M.B., of a son.

**MANSSELL-WOODHOUSE.**—On July 21st, at 18, Beaumont Street, London, W., the wife of Walter Manssell-Woodhouse, M.B.C.S. Eng., L.R.C.P. Lond., of Wantage, Berks, of a son.

**WILLIAMS-FREEMAN.**—On July 23rd, at Weyhill, Andover, the wife of John P. Williams-Freeman, M.D., of a daughter.

## Marriages.

**GILLAM-SKIRMSHIRE.**—On July 25th, at St. Andrew's Church, Holt, Norfolk, Joseph B. Gillam, M.B., B.Ch. Cantab., to Dorothy Jane, elder daughter of J. Trusecott Skirmsshire, M.D., of Holt.

**HORSFALL-CAMPBELL.**—On July 24th, at Holy Trinity Church, Melrose, Chas. E. Horsfall, M.B., of Bedale, Yorks, son of the late Hy. Horsfall, M.D., to Lillias Marianne, daughter of E. Hume Campbell, of Glendarnel.

**HILL-FREND.**—On July 24th, at St. Pancras Church, London, Joseph Shuter Hill, L.R.C.P., M.R.C.S., of 22, Mecklenburg Square, eldest son of the late Samuel Hill, M.D., to Rebecca Billingsley, widow of A. B. Friend, Esq.

**HOWAT-KNOX.**—On July 24th, at All Saints' Church, Bakewell, Robert King Howat, M.B., F.R.C.S. Eng., eldest son of Andrew Howat, Hillhead, Glasgow, to Mabel Mary, elder daughter of John Knox, M.D., Church House, Bakewell.

## Deaths.

**BLACK.**—On July 23rd, at Fete du Lion, Valtournanche, Italy (the result of an accident), Robert Black, M.D., of 14, Pavilion Parade, Brighton.

**GORWALL.**—On July 18th, after a long and painful illness, John Hankinson Gornall, M.B.C.S., L.S.A., J.F., during 21 years Medical Officer of Health of the Borough of Warrington.

**SHETTLE.**—On July 21st, at Nailsworth, Gloucestershire, Richard Charles Shettle, M.D. aged 76, for 28 years Physician to the Royal Berkshire Hospital.

**WAVELL.**—On July 24th, at 83, High Street, Newport, Isle of Wight, Jane Searle, widow of Robert Miller Wavell, M.D., J.F., aged 83 years.

### NINETEENTH CENTURY PROGRESS IN OBSTETRICS AND GYNÆCOLOGY. (a)

By JOHN W. BYERS, M.A., M.D., M.A.O.  
(Hon. Causa);

Professor of Midwifery and Gynecology, Queen's College, Belfast;  
President of the Section.

THIS being the first meeting of the Association held in a new century, it is only natural that we should seize upon the present as a suitable time to look backwards and to ask how have obstetric medicine and gynecology advanced during the Nineteenth Century, a period more fertile in the results of scientific research than that of almost all the years that have gone before. It was during the century that has recently come to a close that the great obstetrician, Simpson, discovered the practical application of anæsthesia in labour, and that the methods of antiseptics and asepsis were gradually evolved; and these two all-important aids have really been the causes of the enormous advances in both obstetrics and gynecology during the past quarter of a century. By their combined help operations (such as the Cæsarean section and symphysectomy) which had formerly been abandoned with regret, owing to their high mortality, have been re-established as recognised safe measures of practice, and many new and improved methods of treatment have been, from time to time, successfully introduced. Conditions which before were regarded as incurable were treated with marvellous success, and, as a result, both diagnosis and technique have been almost revolutionised, because during these operations the obstetrician or gynecologist was brought face to face with situations hitherto undescribed, while, as a further result the morbid specimens removed have given to the science of pathology an enormous impetus by affording an opportunity for the study of interesting material which has not before been described.

In the early part of the Nineteenth Century Nægele's brochure on "The Mechanism of Labour" gave us what Tyler Smith called the "Euclid of Obstetrics"; in more recent years Barbour's "Anatomy of Labour," as studied in frozen sections, has done much to make our knowledge of that interesting process more correct. While the Eighteenth Century will always be remarkable for the work done by William Hunter on obstetrical anatomy as investigated by dissection, the Nineteenth Century has

enormously advanced our ideas of the subject by enabling us—thanks to improved methods—to observe it as presented in a series of frozen sections. By a careful study of these sections, taken at successive stages, we have the whole progress of labour placed before our eyes, and we can follow it step by step as we read the pages of a book. Several of the leaves are still wanting in this volume of sectional anatomy, but, when it is complete, we shall have what I may term a sort of cinematograph representation of the whole progress of labour, which undoubtedly will exercise a most important influence on clinical work. The Nineteenth Century will always have associated with it the practical application of abdominal palpation which is such an addition to aseptic midwifery, by limiting the necessity for frequent vaginal examinations.

It was during the century that is gone that the axis-traction forceps was invented, that the management of the third stage of labour was placed on a scientific basis, and that we have learned better how to deal with such complications as the hæmorrhages which may occur both before and after the birth of the child. Almost all our knowledge of the diagnosis and treatment of extra-uterine pregnancy and of deciduoma malignum has been gained, and by the perfection of other operative measures, craniotomy on a living child has been, we hope, banished. Some in this room remember when it was thought that all lying-in hospitals must be closed owing to their being hotbeds of puerperal fever; at the close of the century we had to admit that in no place is a parturient woman so safe. Turning to the sister science, gynecology, what rapid and brilliant strides it has made in the last twenty-five years! Diagnosis has been rendered more exact by the bimanual method of examination in the dorsal posture. Proper views have arisen as to uterine displacements, and, owing to the success of ovariectomy, not only have thousands of years been added to the sum total of woman's life, but as a result the great triumphs of abdominal and pelvic surgery have followed. Vaginal cœliotomy has been established as a most useful alternative in many cases to abdominal section, and, largely owing to the Trendelenburg position, abdominal hysterectomy for fibroids has become a more and more successful proceeding. Our ideas as to the inflammatory diseases of the appendages and of pelvic hæmatocele have been revolutionised; but with all this enormous progress, there are two subjects about which, unfortunately, we cannot boast—puerperal fever and uterine cancer. It is indeed a terrible blot on our obstetric art, that while within the memory of many of us puerperal fever has been banished from maternities, in which formerly it was so prevalent, the same good results have not followed in general practice. I will give statistics from the three kingdoms,

(a) Address delivered at the opening of the Section of Obstetrics and Gynecology at the Annual Meeting of the British Medical Association at Cheltenham, 1901.

**MORTALITY FROM PUERPERAL FEVER IN ENGLAND AND WALES.**

In 1847-1856 the mortality from puerperal fever was in England and Wales 1·8 per 1,000. It rose to 2·28 in 1875-1884, and to 2·46 in 1886-1895.

The following figures, which I owe to the kindness of Dr. Boxall, who has taken such an interest in this question, give the more recent available statistics.

Year.	Deaths from Puerperal Fever.	Death-rate from Puerperal Fever per 1,000 Births.
1895 ...	1,849 ...	2·0 ...
1896 ...	2,053 ...	2·2 ...
1897 ...	1,836 ...	1·9 ...
1898 ...	1,707 ...	1·8 ...
1899 ...	1,908 ...	2·0 ...

Dr. John Tatham, Statistical Superintendent, General Register Office, has kindly supplied me with the following most interesting details:—

Deaths of women at all ages from puerperal fever and other accidents of childbirth per 1,000 registered births in England and Wales.

1871-80 ...	4·72 per 1000.
1881-90 ...	4·73 "
1891-99 ...	5·12 "

**IRELAND.**

The following return showing the number of deaths in Ireland tabulated under parturition (accidents) and puerperal fever, I owe to the courtesy of Mr. R. E. Matheson, Registrar-General of Ireland:—

Years.	Total.	Death-rate per 1,000 Births Registered.
1895 ...	769 ...	7·2 ...
1896 ...	679 ...	6·3 ...
1897 ...	696 ...	6·5 ...
1898 ...	560 ...	5·3 ...
1899 ...	601 ...	5·8 ...

For the same years the deaths from puerperal fever for the whole of Ireland were:—

Year.	Rate per 1,000 Births.
1895 ...	3·0 ...
1896 ...	2·3 ...
1897 ...	2·1 ...
1898 ...	1·7 ...
1899 ...	2·0 ...

I am obliged to the Registrar-General of Scotland for giving me the following table showing the death-rate from puerperal fever in Scotland during the five years 1895-1899:—

Year.	Number of Deaths.	Proportion in every 100 000 of female population.	Proportion in every 10,000 specified causes of Death.
1895 ...	253 ...	12 ...	62 ...
1896 ...	220 ...	9 ...	63 ...
1897 ...	205 ...	9 ...	52 ...
1898 ...	227 ...	10 ...	59 ...
1899 ...	214 ...	10 ...	54 ...

When we contrast these lamentable statistics with the following returns for the last two years of the practice of the Rotunda Hospital, the largest lying-in charity in the three kingdoms,

**MORTALITY AT THE ROTUNDA HOSPITAL FOR THE YEARS 1898-99 AND 1899-90.**

	1898-99.	1899-1900.
<b>Intern Maternity.</b>		
Total cases ...	1,591	1,560
Total mortality ...	10	6
Percentage mortality ...	0·62	0·38
Mortality from sepsis (2 of these admitted septic) ...	5	0
<b>Extern Maternity.</b>		
Total cases ...	2,163	2,109
Total mortality ...	8	5
Percentage mortality ...	0·36	0·23
Mortality from sepsis ...	2	0
<b>Total cases ...</b>	<b>3,754</b>	<b>3,669</b>

Total percentage ...	0·47	0·27
For two years, total ...	7,423	
Percentage ...	0·39	

they should make those of us who are teachers feel how great is our responsibility, and that our efforts should be redoubled in urging upon students the importance of regarding the process of labour as a natural one, and not to be lightly interfered with unless nature herself should fail, and that if interference became necessary they should use exactly the same antiseptic precautions that they see employed in any gynæcological operation. It is by the observation of these two principles—the avoidance of meddling interference and by the rigid use of antiseptic principles—that we may hope that in the present century the occurrence of puerperal fever will eventually be as rare in private practice as it became in the Nineteenth Century in lying-in hospitals.

The other subject in regard to which, I am afraid, we cannot congratulate ourselves, is cancer of the uterus. How does it originate? Why is it so common? Nay more, why (at least this is my experience) is it becoming more prevalent? These questions surely demand solution. I am reluctantly forced to agree with a statement made by a distinguished American *confrere*, Dr. Baldy, in a paper read before the Section of Gynæcology, College of Physicians of Philadelphia, February 21st, 1901:—“Cancer affecting the cervix uteri is one of the most deadly diseases with which medical men have to deal. By far the largest proportion of these patients eventually die of cancer, be it from the primary lesion or from a recurrence. And this in spite of all that has been done for them either surgically or medically.” No doubt some gynæcologists may say the explanation is that operation is not done early enough, but, as Dr. Baldy fairly asks, “What is sufficiently early?” Every gynæcologist of experience must admit he or she has met with cases where recurrence took place rapidly in what seemed to be at the time of operation a most promising condition, while, again, women with extensive disease have remained well for years after operation. We have passed through the stages of vaginal and of abdominal hysterectomy for cancer of the cervix, but I ask have we up to the present made much real progress? It is not the immediate results of the operation we want to know; it is the subsequent history of the patients. At the present time we can, unfortunately, suggest no other plan of treatment of cancer of the cervix except by operation, but surely we cannot boast much if the statement of Baldy is correct that the most recent statistics, those reported in Cullen’s work on “Cancer,” and the review of cases by Winter of Königsberg, show that in reality less than 5 per cent. of all cases applying for treatment of cancer of the uterus are saved by operation. The obvious lesson is that to ensure any real success we must urge on practitioners the enormous importance of early diagnosis, and that the one symptom which should always be regarded with suspicion is abnormal hæmorrhage. Any woman with abnormal hæmorrhage at any age, and especially if she is over 35 years, demands the most careful clinical examination. Let us hope for greater progress in the future.

Having glanced in what, I am afraid, is a very cursory survey, at the progress of these subjects which specially concern us, let me turn to another question of the greatest interest to the State, as well as to the medical profession. During the present year the public press has been calling special attention to the falling birth-rate. It would appear that in England and Wales, in 1861-71, the birth-rate per

1,000 was 34·8. In 1871-81 it was 34·7, in 1891 it was 31·4 per 1,000, and since then it has steadily gone down, until in the last year of the century, 1900, it was only 29 per 1,000. In 1875, 35 children were born in the United Kingdom for each 1,000 of the population, while in 1900 there were only 29. In other words this means for our population of 41½ millions we are losing 249,000 children annually, and the birth-rate has fallen by 2·67 in the last ten years. The actual increase of the population of England and Wales is due to the fall in the death-rate and the increase of immigration.

We are thus rapidly in England approaching the condition prevailing for some time in France and America. It is not for me at present to discuss the causes of this declining birth-rate, rather my duty is to ask what remedy can we as doctors suggest to combat a state of matters which, from a national and imperial standpoint, must be regarded as unsatisfactory. If fewer children are, in the future, to be born in this country we must redouble our efforts to lower the awful death-rate of infants which, during the first year of life amounts in England to 154 per 1,000, by teaching the people to pay much greater attention to rear their children properly, and by urging the public authorities to provide an adequate supply of pure milk. Our American friends are far ahead of us in such matters, and they showed their usual extraordinary enterprise last summer when they sent pure, non-sterilised milk from various parts of the States (Illinois, New Jersey, and New York) to the Paris Exhibition, where it was actually pronounced better than the average milk sold in the grounds. Quite recently the "Rockefeller Institution for Medical Research," founded by a gift of £40,000 from the millionaire whose name it bears, has decided that the first investigations to be undertaken by the scientific experts connected with it will be to co-operate with the New York Board of Health in studying the milk supply and the contaminated article as a source of danger. But we may also attack this serious problem in another way by taking greater precautions when a woman is pregnant that she may give birth both to a living and healthy child; in other words, we must take more care to combat those conditions which are so dangerous to the child's life before and during its birth. I am afraid it is still too frequently the practice of the present day, when a patient engages a medical man to attend at her confinement, simply to note the engagement, to give a few general directions, or perchance none at all, and, perhaps, in some cases to examine the urine. May I urge that obstetricians should give a much more careful attention to patients who are pregnant, and especially in the case of those looking forward to their first confinement. A pregnant woman, when she engages a doctor to attend her, should be examined as carefully as if she were an applicant for life insurance; in this way he may at an early date detect a flaw in some of her organs (heart, kidney, lungs, &c.), the knowledge of which may lead him to adopt a judicious prophylactic treatment. We should instruct our pregnant patients on such questions as diet, exercise, and management of the secretions; and a most careful examination should be made of the urine from the fourth month onwards, not merely as to the presence of albumen, but in reference to its total amount and the reduction of urea. In this way a form of toxæmia (eclampsia), so fatal to mother and child, may from its early detection be carefully warded off, for it must be admitted that, in the vast majority of cases, the treatment of eclampsia, like post-partum hæmorrhage, is its prevention. Towards the end of gestation a most careful abdominal examination should be made, so that we may learn the position of the fœtus, the amount of liquor amnii,

the presence or not of an abdominal tumour, and, if there is the least suspicion of deformity, the pelvic cavity should be most carefully measured. We must also be on our guard against the dread influence of the syphilitic poison, and the injurious effects of anæmia. In the case of multiparas, an accurate history of previous pregnancies and labours is of the utmost importance. In this way, by a careful, and, if necessary, by a repeated examination of the patient, we may by an early detection of complications ward them off or keep them in such abeyance that their danger is minimised; and if there should be any deformity of the pelvis we can make up our mind what method of delivery is best suited for each particular case. By all these measures we hope that not only a living but a healthy child may be born, and that by our careful management of the patient during and after her confinement no subsequent gynaecological disease may ensue which so often gives rise either to a permanent sterility or to an early subsequent miscarriage.

## THE RELATION OF ALCOHOLISM TO TUBERCULOSIS. (a)

By T. N. KELYNACK, M.D., M.R.C.P.,

Of the Royal Infirmary and the Owens College, Manchester.

ALCOHOLISM and tuberculosis stand foremost among the causes hampering human progress and limiting man's happiness. Through them the evolution of the race has been impeded, and, unfortunately, in spite of numerous restraining and restricting agencies, their baneful influence is still accountable for a high degree of mortality and an immense amount of sickness and suffering.

Three views are possible: (1) That alcoholism is antagonistic to tuberculosis; (2) that alcoholism bears no special relation to tuberculosis; (3) that alcoholism definitely predisposes to tuberculosis.

### I. ALCOHOLISM ANTAGONISTIC TO TUBERCULOSIS.

Before the true nature of tuberculosis became apparent, the opinion was somewhat widely held that habits of alcoholic excess were antagonistic to tuberculosis and even preventive. This impression still exists among a large section of the public, and is apparently in part due to opinions expressed by many of the earlier writers on pulmonary tuberculosis. Indeed, in some medical quarters such a view is still held. This view was clearly expressed by Dr. Richard Payne Cotton many years since in his Fothergilliam Essay: "It is worthy of remark that the habitual drunkard—he who is always in his cups—is not very often the subject of phthisis; such, at least, is the result of my own observations." The idea that alcoholism was antagonistic to tuberculosis may, perhaps, in part account for the advocacy of its persistent and even excessive use in phthisis.

The abolition of alcohol from many modern sanatoria, however, seems to indicate that, as Dr. Ransome well expresses it, "Owing to the terrible consequences of excess, and to the proclivity of mankind to its excessive employment, it (alcohol) can only be recommended in selected cases with many cautions." (b)

II.—Many hold that alcoholism bears no special relationship to tuberculosis and only exerts an indirect influence in so far as it leads to a lowering of general vitality and places the individual under conditions particularly favourable to the infection of tubercle. And certainly the circumstances attending the life of the chronic alcoholic are

(a) Abstract of paper read before the British Congress on Tuberculosis.

(b) "The Treatment of Phthisis." By Arthur Ransome, M.D. London, 1896. P. 94.

generally such as to specially expose him to the risks of tuberculosis. His habits lead in great measure to an indoor existence, the maintenance of an insanitary environment, insufficiency of suitable food, oftentimes to the influence of depressing emotions; and not infrequently his indulgence necessitates his following an occupation under conditions which are peculiarly inimical to health. Thus, while the influence of overcrowding, neglect, uncleanness, malnutrition, and nerve influences cannot be overlooked, very considerable difficulty attends any attempt to estimate the effect of alcohol *per se* in rendering the tissues peculiarly vulnerable to the tubercle bacillus.

III.—The view that alcoholism definitely predisposes to tuberculosis has of recent years received much support. Indeed, the tendency of modern opinion is to recognise alcohol as an agent, which renders the tissues specially prone to tuberculous infection.

The close association of tuberculosis and alcoholism has now been widely recognised, not only by British physicians, but also particularly by American and French observers. Various suggestions have been made in explaining the liability of alcoholics to tuberculosis. There can be no doubt but that the non-hygienic surroundings and nutritional impairment and lowered vitality of the drunkard greatly predispose him to tuberculous invasion. But it is contended by some that, even besides these factors, there are special influences arising from the action of the alcohol and its associates. Professor Sims Woodhead has recently shown that alcohol has a marked influence in altering or determining alteration of the cells of animals subjected to the action of certain pathogenic organisms. Professor Abbott, of Pennsylvania, and also Dr. Deléarde, working in the Institut Pasteur at Lille, have recently shown that alcoholised animals are more readily infected by many organisms than non-alcoholised animals, and other investigators have also shown that alcohol produces a marked negative chemiotaxis. It has also been found that animals brought into a state of chronic alcoholism are much less readily rendered experimentally immune to microbial infection. Attempts have also been made to show that alcohol, through its influence on nervous structures, rendered the tissues, and especially the lungs, prone to invasion by tubercle. (a)

IV.—In order to compare some of our Manchester experience with the views and opinions above indicated, I have endeavoured to analyse and express the results of observation of hospital cases for a number of years. A reference to pathological data probably affords the most reliable basis for the formation of sound views as to the relationship of alcoholism and tuberculosis.

#### ALCOHOLIC NEURITIS AND PHTHISIS.

Some time since I analysed a number of fatal cases of peripheral neuritis occurring in chronic alcoholics. Eight cases were subjected to pathological examination during a period of three years; they formed 1.6 per cent. of all the medical cases examined during that period. Pulmonary tuberculosis was met with in seven. This gives a percentage of over eighty-seven. All the cases were females. In only one subject were there distinct tuberculosis lesions elsewhere than in the lungs, and then the intestines were also affected. In one subject there was an old tuberculous focus at the apex of the lung, but it seemed probable that the active phthisis was rather due to a fresh infection than from this latent patch. In five cases both lungs were more or less involved; in two

the left was the only one showing any distinct tuberculous process; in three of the cases the course seemed to have been rapid; in four it seemed to have lasted for several months. One subject, it was stated, had "spat blood" six months before her death; in one case one lung only was studded with small tubercles, the injection evidently having been recent; in two there was more or less extensive caseation; four presented evidences of softening and cavitation; and in two of these there was some fibrosis. (a) Since collecting the above I have gone over my more recent pathological notes. Two further cases of alcoholic multiple neuritis have come to autopsy. In one, a male, *æt.* 35, the subject also of hepatic cirrhosis, both lungs were studded with recent tubercles. There was no softening, but caseous foci at the apices were apparent of older formation than the tubercles elsewhere. In the other case, a female, *æt.* 32, in whom there was also a fatty and cirrhotic liver, the lungs, although congested, œdematous, and presenting patches of broncho-pneumonia, showed no distinct evidences of tubercle. Thus out of ten fatal cases of alcoholic neuritis—nine females and one male—eight, or 80 per cent., were the subjects of pulmonary tuberculosis.

In connection with the recent remarkable outbreak of arsenical neuritis in Manchester and district, and occurring principally in alcoholics among the poorer classes, it is interesting to note that in a considerable number of the fatal cases active pulmonary tuberculosis was present, and in some undoubtedly much hastened the end.

Tuberculosis is also of frequent occurrence in the subjects of alcoholic cirrhosis of the liver. In many cases it is manifestly of the nature of a terminal infection.

In order to throw light on this matter, the records of 3,053 medical cases examined in the Pathological Department of the Manchester Royal Infirmary have been analysed. I have collected 121 examples of common cirrhosis of the liver. All doubtful and complicated cases were omitted. Cases associated with cardiac or such chronic affections as seemed to have led to secondary changes in the liver were excluded. All examples of "biliary" cirrhosis and those in any way connected with syphilis have been passed over. After omitting several doubtful cases, in 28 tuberculosis—either active, latent, or obsolete—was present. Thus over 23 per cent. presented evidences of tuberculosis, active phthisis was present in 14, 12 males and two females; and active peritoneal tuberculosis in 12, nine males and three females. Of these, six males and one female had involvement of both lungs and peritoneum. In five males and one female the lungs alone were affected, and in two males and two females the peritoneum alone. No less than 12, or nearly 10 per cent. of the 121 cases, appeared to die directly from tuberculosis. The average age of those in which active tuberculosis was limited to the lungs was just over 44 years.

#### AN INVESTIGATION INTO THE PRESENCE OF INFECTIVE MATERIAL IN DWELLINGS OCCUPIED BY CONSUMPTIVE PERSONS. (b)

By HAROLD COATES, M.D., D.P.H. (Vict.),  
Senior Assistant to the Medical Officer of Health for the City of Manchester.

It is now eleven years since Cornet published the

(a) Kelysack, T. N. "On the Occurrence of Pulmonary Tuberculosis in the Subjects of Alcoholic Neuritis."—*The Medical Chronicle*, 1895-6. Vol. iv., pp. 180.

(b) Abstract of Paper read in the State Section of the British Congress on Tuberculosis.

(a) See "Pulmonary Consumption, Pneumonia, and Allied Diseases of the Lungs." By Thomas J. Mays. New York, 1901. Pp. 61.

result of his investigations into the infectivity of the dust found in the dwellings of consumptives in Berlin, and up to now no work of a similar character has been done in England. In 1895 an investigation of this kind was commenced under the direction of Professor Delépine at Owens College, but was interrupted by other engagements. The establishment of a scheme of voluntary notification of phthisis in 1899 presented a favourable opportunity for taking up the investigation, and acting on the suggestion of Dr. Niven, for whose administrative scheme the reliability of Cornet's results was all important, the Hospitals Sub-Committee of the Manchester Corporation resolved that I should carry out the work under the direction of Professor Delépine, who had previously offered me special facilities for resuming this investigation. Although the plan of the investigation is somewhat different, the methods of experimentation were, in the main, similar to those of Cornet, although modified in some respects at the suggestion of Professor Delépine.

Specimens of dust were collected from situations in which dust from the atmosphere had settled naturally, and where there would be no likelihood of direct contamination with expectoration or by infected articles, except in the disinfection experiments.

The method employed to determine the presence or absence of tubercle-bacilli in the dust was that of the inoculation of a susceptible animal, viz., the guinea pig.

The houses in which investigations were carried out are classified into the following groups:—I. Houses which are in a dirty condition, and in which a consumptive patient is living who is taking no precautions to dispose of his expectoration so as to prevent infection of the atmosphere, but who spits freely on to the floor, or into his pocket-handkerchief, &c. II. Houses which are in a very clean condition, but in which a consumptive patient is living who is not sufficiently careful as to the disposal of his sputa. III. Very dirty houses, in which there has been no case of tuberculous disease for several years past.

In every house the following details were noted:—1. Date of visit. 2. Dimensions of the room examined. 3. Number of persons habitually occupying the room. 4. The conditions of light and ventilation. 5. The state of the walls, floor, and ceiling as regards construction and freedom from dust and dampness. 6. The presence or absence of carpets, curtains, or other objects which afford lodgment for dust. 7. Length of time patient has lived here, and duration of illness. 8. The presence or absence of visible signs of contamination, such as patches of recent or dried sputum on floors, walls, &c. 9. The situations from which dust was taken—always from such a place that direct infection with sputum would not occur.

HOUSES TO CLASS I.

Infected houses in a dirty condition. Twenty-three houses of this class were examined, and in 21 definite results were arrived at. In 13 of these houses at least one animal was found to be tuberculous, and in another house (No. 6) tubercle-bacilli were present in the dust; and, therefore, in 14 out of the 21 houses, i.e., in 66.6 per cent., the presence of infective dust was proved which had at one time been suspended in the atmosphere, and, therefore, was capable of being inhaled. In seven of the houses there was no evidence that the dust was infective.

Altogether, 52 guinea-pigs were inoculated with dust from these houses:—20 of these died within a few days of inoculation; 17 were killed four or five weeks after, and found to be tuberculous; 15 were

killed four or five weeks after, and found to be healthy.

The large proportion of houses—66.6 per cent.—in which the presence of virulent tubercle-bacilli was proved shows what a dangerous accumulation of infective material there is in this class of house.

The effects of overcrowding are not apparent in these results, possibly because the series of houses is too short. In the 14 rooms in which positive results were obtained the average cubic space per head is 457 cubic feet, while in the cases of the seven rooms which did not yield positive results the average cubic space per head is less, viz., 368 cubic feet. The cubic space per head is chiefly of importance in connection with the provision made for renewal of the air of a room. A large cubic space is of little avail if the ventilation is bad. The effects of fresh air and sunlight on the vitality of the tubercle-bacillus are well known. Taking the conditions of lighting and ventilation in these 21 houses which gave the results either negative or positive, we find that out of the 14 positive houses the lighting and ventilation was bad in eight houses, fair in one house, and good in only five; while of the seven negative houses, the lighting and ventilation was good in six and fair in the other one.

In none of the houses with negative results was the lighting or ventilation poor or bad. These facts point strongly to the beneficial effects of light and air, even in the dirtiest houses, where the conditions are certainly not favourable to their action.

In 16 of the houses samples of dust were obtained at different elevations in the room, so as to learn at what points the most dangerous accumulations of infective material was to be found. As was to be expected, those samples of dust taken within one or two feet of the floor produced tuberculosis oftener than samples taken at higher elevations. This greater infectivity of the dust nearest the floor was not due to direct infection with sputum, as all the samples were collected from places where this could not occur. Certain parts of the floor, e.g., near the bedside and near the fireplace in the living room, are the places where the sputum is deposited in largest amount, and where the pulverisation most readily occurs.

SERIES II.—CLEAN BUT INFECTED HOUSES WERE NEXT INVESTIGATED.

Houses which are in a very clean condition, but in which a consumptive patient is living, who is not sufficiently careful as to the disposal of his expectoration. Ten houses of Class II. were brought under examination, and two samples of dust were taken from each house, and each sample was used to inoculate one guinea-pig. Twenty guinea-pigs were inoculated, and of these only three died from acute diseases shortly after inoculation. Of the remaining 17 animals, six developed tuberculosis, and 11 were found free from tuberculosis at the post-mortem examination.

Of the 10 rooms examined, dust capable of producing tuberculosis on inoculation into a susceptible animal was found in five; in one case both animals belonging to that room became tuberculous; in the other four rooms one animal only became affected. Thus, even in the cleanest of houses infectious dust can be found in 50 per cent. of cases when the phthisical occupant is using his pocket-handkerchief or the floor as a receptacle for sputum. It is therefore evident that ordinary cleanliness alone is not sufficient to prevent the accumulation of infectious material in the rooms occupied by a consumptive. The average cubic air space per head in these rooms where infective dust was obtained was equal to 336 cubic feet, and in those rooms which gave negative results 506 cubic feet. In the five

houses where the dust was not infective, in every instance the lighting and ventilation was good. On the other hand, of the five houses which gave positive results on inoculation of their dust, only one had good lighting and ventilation, two had bad light and ventilation, and in two the lighting and ventilation were described as fairly good. Taking the houses of Class I. and Class II. together, the influence of sunlight and fresh air in the prevention of accumulations of infective dust is shown very markedly. In these houses, also, the tendency of the infective dust to settle towards the lower parts of the room is shown.

I have examined 33 houses, of which no definite results have been obtained from two, leaving 31 houses for purposes of comparison.

These results are seen in the following table:—

BERLIN.			
Number of houses examined.	Positive results.	Negative results.	Percentage of positive results out of total.
28	19	9	67
MANCHESTER.			
31	19	12	61

These experiments show that there is a large amount of highly-infective material present in dwelling-houses which are inhabited by consumptive patients who do not take the necessary precaution to destroy their expectorations. Any house where there had been a case of bronchitis or lung affection, meningitis, marasmus, strumous glands, or any case of bone tuberculosis, was excluded. This part of the work was really the one which involved the greatest amount of labour and care, as a very large number of houses had to be investigated before a sufficient number could be obtained in which these requirements were complied with.

The houses chosen for these investigations were all very dirty, and were exactly similar to those of Class I., except that the consumptive patient was absent. Many of them were badly lighted and ventilated, and in all of them there was plenty of dust and dirt on the walls, floors, &c. Ten houses were examined, and in no case was any tuberculous dust discovered.

Twenty guinea pigs were inoculated with dust taken from these houses, and six of these died within a few days of inoculation. The remaining fourteen were killed four to five weeks after inoculation, and all were found free from tuberculosis. These results, taken in conjunction with the results obtained from houses in Class I. and Class II., show that the virulent dust found in those houses is due to the presence of a consumptive patient, who is infecting the atmosphere with his expectorations. These experiments show that living and virulent tubercle-bacilli are present in the dust, which has deposited itself naturally from the atmosphere, in rooms which are occupied by phthisical patients who are in the habit of spitting upon the floor or into pocket-handkerchiefs. They also seem to show that this infective dust is present in greatest amount or is most virulent where the access of sunlight and the free circulation of air is prevented. Such infected rooms must be a source of danger to those occupying them. Healthy persons run the risk of being infected, and the patient himself may become reinfected and his ultimate recovery be delayed or prevented.

It is well known that the tubercle-bacillus can retain its virulence for months in the dry state; it is evident, therefore, that these houses will remain

infective for some considerable time after a patient leaves it. Unless there are some measures taken to remove this infective dust, a new tenant coming into a house lately occupied by a consumptive patient is exposed to the danger of acquiring phthisis. In the poorer quarters of large cities, where houses are too few for the needs of the population, the new tenant often takes possession the same or the following day that the late tenant leaves, and nothing in the way of disinfection or cleansing the walls and ceilings is done. There is no doubt that many persons are in this way unknowingly exposed to infection, and an infected dwelling is in many cases the origin of a case of phthisis which the most careful inquiry has failed to trace to any direct association with a previous case. The same danger exists to some extent at the boarding houses and hotels at health resorts.

Samples of dust collected from various public places have also been examined. Five specimens of dust were collected from the walls at various elevations of the waiting-room of the out-patient's department of the Hospital for Consumption in Manchester. This waiting-room, which is a lofty, well-lighted, and well-ventilated hall, is used by 180 patients every morning. Ten guinea pigs were inoculated and killed five weeks afterwards. None of them showed any signs of tuberculosis. Five samples of dust were also examined from the waiting-room of one of the large general hospitals, but here also the results were negative. Dust taken from railway carriages failed to produce tuberculosis, but two samples taken from a general waiting-room at a railway station both produced tuberculosis.

The method of disinfection in use in Manchester is one recommended by Professor Delépine eight years ago, as a result of experiments which he carried out to test the efficiency of various disinfecting processes. The method is that of disinfection by a solution of chlorinated lime of the strength of  $1\frac{1}{2}$  ozs. to the gallon.

## INJURIES OF JOINTS WITH SPECIAL REFERENCE TO THEIR IMMEDIATE AND REMOTE TREATMENT BY MASSAGE AND MOVEMENT. (a)

By HOWARD MARSH, F.R.C.S.,  
Surgeon to St. Bartholomew's Hospital.

BOTH massage and movements have long been employed in English surgery, but lately they have come into much more general use. Both are valuable remedies, but if used as a matter of routine both may do great harm. As methods of surgical treatment they must always be closely supervised, care being taken to watch their effect, and especially to be sure that no element is present in the case which renders their employment undesirable.

*Physiology of Massage.*—It is necessary to have a clear idea as to what has been termed the Physiology of Massage—as to the different ways, *i.e.*, in which it acts.

1. It enlarges the amount of blood circulating through the part concerned. This is obviously apparent in the skin, which, instead of remaining cold and pale, becomes warm, and more or less red. The same result was experimentally demonstrated in regard to the muscles by Brunton and Tunnicliffe, who showed that the amount of blood passing through them both during massage, and after its cessation, was increased. This increase of blood is in every way advantageous. It maintains or improves the nutri-

(a) Introduction to a discussion, Section of Surgery, at the Cheltenham meeting, July, 1901.

tion of all the various tissues; it promotes the restoration of the functional activity of injured muscles, and it plays an important part in the absorption of lymph and extravasated blood.

2. Its action is mechanical. By kneading and percussion, extravasated blood and lymph which have been coagulated in the tissues, and have led to brawny oedema, are broken up and dislodged, while by stroking from below upwards they are swept onwards and brought within the reach of healthy lymphatics and a normal venous circulation, so that they can more readily be absorbed.

3. It is an efficient stimulant to damaged muscles through its influence on the nervous system. In such minor injuries as sprains and contusions, probably the small nerves ramifying in the injured part are seldom torn across, for they are tough rather than brittle, they are well protected in the subcutaneous tissue and the deeper structures, and their course is tortuous, so that they are quite easily put on the stretch. Nevertheless they are not infrequently so far injured that their functions, for the time being, are more or less suspended, and massage is then a very useful agent in stimulating them to a resumption of activity. It probably acts in a similar manner on the vaso-motor nerves, which preside over the arterial system of the part.

4. No one who has watched its sedative effect when applied in cases of recent injury can doubt the influence of massage in reducing muscular spasm and relieving pain. Here it must be used very gently and be limited to stroking and light friction for short periods three or four times a day.

5. Probably massage promotes the absorption of recently formed adhesions provided they are not too extensive and firm. This is a matter of considerable interest. Just as provisional callus, formed in the repair of fractures, is absorbed, so is the new connective tissue which is developed after injury of the soft parts. Perhaps the most obvious instance of this is met with in the case of adhesions following peritonitis. Even extensive adhesions gradually yet completely disappear, probably as the result of constant disturbance and traction during peristalsis. Much the same result is produced by what may be termed the interstitial disturbance and traction which takes place during the different movements employed in massage.

*As to Movements.*—These are of three kinds: those performed under an anæsthetic; passive movements and voluntary movements on the part of the patient, often carried out against resistance. As to movements under an anæsthetic they can be safely applied only when a careful diagnosis has been made. In the first place it must be ascertained that the joint itself is not, nor has been, actively diseased, so that it has undergone no considerable structural changes, such as follow tubercle, or osteo-arthritis, septicæmia, or locomotor ataxia. The cases in which this form of movement is most successful are those in which the joint itself is practically healthy, while it is hampered by changes in the parts around. Passive movements are chiefly useful in restoring movements that have been lost, or in preventing stiffness in joints which are to be long disused, for instance, a healthy ankle, the patient having disease of the hip or knee. Voluntary movements on the part of the patient, especially when performed against resistance, are in many instances more valuable than massage. Several forms of apparatus have been introduced for use in these movements, and many of them are very satisfactory. In all cases, however, efficient supervision must be maintained.

*Diagnosis.*—Diagnosis is, of course, of essential importance. It cannot always be exact, but it must be carried far enough to indicate that the case belongs

to the general class in which these agents are useful, and that no element is present which renders them unsuitable. The conditions for which massage and movements are suitable are sprains and contusions of previously healthy joints unattended with any serious complication such as dislocation or a fracture, any wide laceration of muscle, rupture or displacement of tendons, or such pre-existent conditions as tubercle, gout, or hæmophilia.

The treatment of recent fractures by massage was so fully discussed at the meeting last year at Ipswich that it is needless to consider it now. The after treatment of dislocations has of late years undergone a great and very advantageous change. In the case, *e.g.*, of the shoulder, the arm is no longer bandaged to the side for a fortnight or three weeks, but passive movements and massage are regularly used after the second or third day. I have seen a patient thus treated able to move his arm freely in every direction in the course of three weeks. I have also seen a patient walk freely and without lameness three weeks after the reduction of a dislocation of the hip. The chief symptoms which indicate the use of massage and movements are stiffness and pain; but before they are employed the cause of the symptoms must be ascertained, as to whether the mischief is inside or around the joints. Take the shoulder. The arm may be stiff and there may be severe pain and marked muscular wasting. Is this a case of disease of the joint itself or of adhesions outside? There is, I believe, only one test to be relied on to determine this question. This is to ascertain whether the joint is as stiff as it at first sight appears to be, or whether, within certain limits movements are free and smooth. If these free and smooth movements—limited though they be—are present, the fact is a strong indication that the joint is sound, and that the symptoms depend on surrounding adhesions. Cases in illustration are related. As to pain it is very important to remember that it cannot be used to differentiate between real joint disease and surrounding adhesions. Indeed, in many cases the relaxed pain due to adhesion is more severe than that produced by joint disease. Muscular wasting—a principal symptom in disease of a joint—may be present, though the case is one of mere adhesion in the capsule and surrounding parts. In some instances movement under an anæsthetic will produce a cure which there seemed at first sight no reason to anticipate, for though the patient complains of “weakness” and pain in the joint there is no appreciable stiffness or any condition for which movement and massage seem called for. These cases, which bone-setters not rarely cure, by moving them as they move all others, are instances of slight adhesions which cannot be detected, but which are yet sufficient to make the patient walk with lameness and “weakness” of the joints concerned. Cases are related to illustrate this group.

## THE PHYSICAL BASIS OF MELANCHOLIA. (a)

By JOHN TURNER, M.B.,

Assistant Medical Officer to the Essex County Asylum, Brentwood.

CERTAIN of the nerve cells of the cortex present an alteration in appearance in many cases of melancholia and dementia (alcoholia). The change is similar to that which follows when the axons of the fore-horn cells or those of the pontiæ nuclei have been severed. But examination of the axons (in the cord) shows that in melancholia the change is not

(a) Abstract of paper read at the Cheltenham Meeting of the British Medical Association, July, 1901.

produced primarily by interference with the axons. The change has also been noted in melancholia by Wigglesworth and others.

The distribution of the lesions were as follows:—The pyramidal and giant cells of the so-called motor cortex show it most clearly; in this region most of the cells being affected. It is commonly met with in the frontal and occipital regions, especially in the large cells of the latter. Of all the nuclei examined in cross sections of the medulla oblongata - hypoglossal - vagus - lateral, ambiguum, gracile, and cuneate, only the first escapes, all the others show the change affecting generally the major proportion of the cells.

In the cord the cells of Clarke's column are early affected and ultimately in advanced cases the fore-horn cells.

In the posterior-spinal ganglia, while only a few cells show the change yet many are altered in another way—densely stained and very shrunken.

In the tracts of the cord only in very advanced cases is there any sign of degeneration of the myelin sheaths, and then it is the crossed pyramidal tract (axons of motor cells of cortex) which is affected.

The pathological observations indicate that the cause which brings about this change is not a general one, operating on all parts of the nervous system, such, e.g., as a perverted state of the blood, otherwise we should expect to find all the cells of a similar type participating in the change. This, as has been shown, they do not. Another point brought out is that the change early affects the afferent cells, and notably those of Clarke's column.

The experiments of Warrington show that this change can be produced in the cells of Clarke's column by division of the posterior roots, and he assumes that in this case it is due to depriving these cells of the ingoing stimuli normally passing to them.

Thus it has been established experimentally that this change can be set up in at least two ways.

1. By agents having a destructive action on the axons of the cells in question (traumatism, and probably also alcohol) and

2. By agents which do not primarily affect the axons of the affected cells

These observations indicate that the melancholic cases fall into the latter class, and, further, that the state of the mind is an essential factor in inducing the change.

The deprivation of the nerve cells of their normal ingoing stimuli is the explanation offered in accordance with the writer's hypothesis (*Journal of Mental Science*, July, 1900) that melancholic states depend on dissolutions of the nervous system affecting the sensory or ingoing section of the nervous reflex mechanism. Clinical observations from Griesinger and other are also given in support of this contention, notably the very general occurrence of anaesthesia in melancholia.

### SOME CONDITIONS OF SUCCESS IN THE TREATMENT OF NEURASTHENICS. (a)

By Dr. A. T. SCHOFIELD,

Honorary Physician to the Friedenheim Hospital, and Victoria Homes.

As this paper deals with treatment only, the word neurasthenia is here used to include all functional nerve cases.

The hints given are grouped around four centres—the physician or the personality, the patient or the

diagnosis, the methods of treatment, and various details.

With regard to the physician, then, sympathy is one of the first conditions of success. It need not be shown, but if felt by the doctor it is felt by the patient, and inspires him at once with confidence. One cannot feel it till one has grasped the fact that a disease of the imagination is not an imaginary disease. The next qualification is *patience*, for want of which number of sufferers remain unrelieved. Allied to this is *perseverance*. Many a successful line of treatment fails to succeed from lack of this. Another is firmness in essentials combined with flexibility in non-essentials. The next quality is tact in mental touch, the "tactus eruditus." Another quality is honesty, not in its mere literal meaning so much as the power of acting solely in the patient's interests as distinguished from that of their families or friends. And lastly, success in the physician depends upon a mind that possesses both the powers of observation and of imagination. Many have the one or the other, but to possess both the gift of accuracy in details with broad and wide views is to be a master in one's profession.

With regard to the patient the point first to decide is the relative part played by mind and body in the disease.

Setting aside so-called "mental cases," we get in "hysteria" lesions of the sub-conscious mind, and in neurasthenia proper, a physical disease of the nerve centres in brain and cord.

The value of these distinctions becomes obvious in treatment.

The distinction between the three groups is not, as a rule, difficult. What is much harder is to discern on which basis of coarse physical lesion the nerve troubles may rest, and this is a point frequently overlooked. Another point with regard to the patient is that he should not have been already a victim of many failures. If he has, the difficulties of cure are greatly increased. Another element of success is confidence in the doctor and nurse. The two indeed must mutually uphold each other, or the most powerful means of cure are neutralised. Again, a correct estimate must be made of the patient's personality and mental calibre, a factor which in the case of ordinary diseases may, as a rule, be neglected. In all these cases the possible sexual basis of some of the symptoms must never be forgotten.

As to methods of treatment, these must be cured away from home; which however much it may at times be a place of rest to men is never so to women, as it is the sphere of their work, and all new cases require rest of some sort. A good nursing home is a *sine qua non*, and is by no means easy to get.

The nurse is a still more difficult factor in the cure. As a matter of fact, while mental attendants and hospital trained, certificated, and chartered nurses abound, the neurasthenic nurse is a rare being to find, and her serious training has hardly yet been evolved.

Finally with regard to details. While, in ordinary cases, rest in bed is nearly always part of the cure, in any with a true mental taint, however slight, it nearly always does harm. Isolation is another point that requires intelligence and not routine in its application, being not always desirable.

Massage is, in most cases, a necessity to aid digestion, but besides this it is of special value in disorders of circulation, wasting or weakness of muscles, stiffness or weakness of joints, pain, congestion of internal organs, and many forms of cardiac disease.

Suggestions play a large part (without any question of hypnotism) in these cases, but seldom can be assimilated in a raw state, but have to be combined

(a) Abstract of Paper read at British Medical Association, Cheltenham, July, 1901.

with various forms of treatment. The management of dyspepsia, sleeplessness, constipation, restlessness, depression, and convalescence, all have an important bearing on the success of the treatment.

Finally, it may be said that the successful nerve doctor owes less to his teachers and more to his idiosyncrasy, experience, and applied common sense than any other variety of medical man,

### Clinical Records.

#### TREATMENT OF WHOOPING-COUGH BY NASAL IRRIGATION.

By EDWARD MAGUIRE, M.D., D.P.H.

FORMERLY the treatment of whooping-cough was most annoying and unsatisfactory to the medical practitioner. Now, I think we may hope we are on the proper track to combat and conquer this most serious and distressing disease. I have for a long time been of opinion that the fountain and origin of this complaint were located in the Schneiderian membrane, and this belief was strengthened by the report of a case by Dr. E. M. Payne, which appeared in a medical journal some weeks ago.

Acting on this hypothesis I have recently treated two cases, a little girl, aged 2 years 3 months, and her brother, aged 10 months, by irrigation of the nares with warmed carbolio lotion in the manner and with results as shown below.

There can be little doubt that the disease is produced by a specific organism, as Afanasjew discovered large numbers of bacilli in the sputum in this disease, and Hewlett, in his "Manual of Bacteriology," says, "Koplik, by sowing the pellets on solidified hydrocele fluid, obtained a pure culture of a small and delicate bacillus measuring 0.8 to 1.7 ins. in length." The bacilli being found in the sputum could be accounted for by the escape of mucus by the posterior nares or by the extension of the disease from the Schneiderian membrane to the pharyngeal or laryngeal membranes.

The strength of the lotion I used was 1-40 with a little glycerine added. I procured a two-ounce syringe with a rubber nozzle, so that when it was in the nares it could not hurt, no matter how the child struggled. Three fills of the syringe were injected into each nostril three times a day. I had only once to show the mother how to use the syringe, and afterwards she and the nurse had very little trouble in using it, although the children were very young. It is a good plan to bind down the arms with a towel or binder before using the syringe.

The following diary, kept by the mother, shows the result of this treatment commenced June 29th:—

The result in both cases tends to prove that treatment directed to the Schneiderian membrane by thorough irrigation diminishes the frequency of the paroxysms and coughs, and reduces the duration of the disease from months to weeks. Of course, one must not disguise the fact that in this mode of treatment there is a risk of some of the fluid getting into the Eustachian tube.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 3rd, 1901.

At the German Congress of Medicine, Hr. Hirschberg gave an address on the

#### OPERATIVE TREATMENT OF HYPERTROPHIC CIRRHOSIS OF THE LIVER.

Our knowledge of the disease was so limited that treatment has not come to the front. In one case, that of a man, æt 51, with great enlargement of the liver, he had achieved a success, that had now lasted for over a year, by operation. Previous to the operation, cirrhosis could not be diagnosed to a certainty. It was rendered probable by the slow development of the disease, by the steady enlargement of the liver, the great and early enlargement of the spleen, the intra-hepatic retention of gallstones, the absence of ascites and of enlargement of superficial abdominal veins, even in an advanced stage of the disease, and finally the fever and the rapid pulse, amounting at times to tachycardia. At the operation the speaker's idea was to conduct the pent up bile to the outside in order to obviate further damage to the liver structures. After cutting into the abdomen he made an opening into the liver the length and breadth of a finger, out of which bile flowed freely. The canal in the liver was plugged with gauze. After its removal a fistula remained which closed at the end of a month. The operation was well borne, and the patient had since gained 25 lbs. in weight.

Hr. Naunyn was not a pessimist as regarded the disease, as recovery in both forms was not so very rare. But he was doubtful whether Hirschberg's case was really one of hypertrophic cirrhosis of the liver. The induration of the liver meant an infection but not purulent cholangitis, a disease that was amenable to treatment of a surgical kind.

Hr. Rosenstein, Leyden, in about 150 cases had never seen a recovery. He also doubted the accuracy of the diagnosis, as there was no jaundice. As regarded the tachycardia the patient might have had cardiac dilatation with liver stasis. It had not been shown, therefore, that operation would be useful in hypertrophic cirrhosis of the liver.

Hr. Hirschberg, in reply, said he must maintain the accuracy of the diagnosis, as the type of the disease could not be otherwise grouped. Hanot himself had acknowledged that there could be hypertrophic cirrhosis of the liver without jaundice. In the bile that escaped through the fistula the bacterium coli was found, but its pathogenic action could not be established.

Hr. Alex. Ellinger spoke on

**THE INFLUENCE OF RENAL INJURIES ON THE COURSE OF PANCREATIC DIABETES IN THE DOG.**

The inquiry was conducted in conjunction with Hr. Seelig. The results were the following: In a case of pancreatic diabetes in the dog acute nephritis was set up by injection of cantharidine, the quantity of sugar in the urine diminished. Not only the percentage and absolute quantity of sugar was diminished, but the proportion between the excreted sugar and the nitrogen became considerably smaller. This influence of the cantharidine on sugar excretion passes away much more quickly than the excreted albumen. If acute nephritis developed spontaneously in a pancreas diabetic dog, the quantity of sugar in the urine diminished, and it could disappear entirely. The disappearance of the sugar depended on efficient excretion from the kidneys, as the quantity of sugar in the blood itself was increased.

Hr. Nannyn intended to apply the experiment to the human subject. He referred to a large number of sugar determinations in the blood of diabetics, where in cachexia the sugar was not increased, but rather lessened, and also to a large number of observations wherein people who had become cachectic (from tuberculosis, for instance), had lost their sugar, although there was no evidence present of renal disease. People who showed sugar reaction whenever small quantities of bread were taken bore large quantities without any excretion of sugar.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 3rd, 1901.

**PROTHESIS FOR INCONTINENTIA URINÆ.**

SOME time ago Gersung drew attention to the use of paraffin as a means of obviating the distressing condition of urine incontinence. It is maintained by some that the poison readily passes into the system, their belief being inferred from the nature of the accidents that have sometimes followed these injections. By others it is held to be a dangerous procedure in that it tends to the formation of fatty emboli, which produce serious results when located in the brain.

After extensive practice with paraffin the author is more confident than ever that its use is safe, useful, and beneficially lasting in effect. It should be injected in a semi-fluid condition, with a hypodermic syringe which causes no irritation. It is neither rejected nor absorbed for a very long time, by which time the parts are so changed as to require no further treatment. He relates many cases cured by this method which had defied all operative ingenuity.

**TOTAL EXTIRPATION OF THE VAGINA.**

Wertheim related two cases in which the vagina was removed entirely, together with the other organs of generation, and without any subsequent trouble. After closing the abdominal wound he incised all round the vaginal aperture, and removed the canal *in toto*.

This opinion is confirmed by Guénard, who maintains that the hæmorrhage is easily controlled. He states that he extirpated for myoma and only required three ligatures! The operation, moreover, can be performed in a very short space of time, which is very important in such cases.

**GANGRENE OF LOWER EXTREMITIES.**

Burchard relates a case of some interest in midwifery. Having a breech presentation an effort was made to ease the head by dragging on the body which resulted in decapitation of the fetus. In removing the head an incomplete rupture of the uterus occurred which subsequently left a hæmatoma in the broad ligamentum, and finally a thrombus in the popliteal veins followed by gangrene, for which both legs had to be amputated. The patient ultimately recovered.

**BLENNORRHEA NEONATORUM.**

Zweifel assures us that he has tried all the reputed drugs, including the latest, protargol, without success as a prophylactic in ophthalmia neonatorum, and concludes that nothing succeeds so well as acetate of silver in the form of 1·2 per cent. solution. This may be applied to the eyes without causing pain, the eyes being subsequently washed with a solution of sodium chloride. He instructs all the midwives after washing the child to instill a few drops of the acetate solution wherever (a) there is a history of a previous white discharge, (b) if the same mother has had previous children suffer from ocular discharges, (c) in the case of children whose parents are not particularly clean.

**OBESITY AND THE BANTING TREATMENT.**

A case of Stadelmann's has excited a good deal of interest here, and is worth briefly relating. The patient was a heavy drinker and suffered from alcoholic polyneuritis, yet in spite of the atrophic paralysis of the lower extremities the body weight increased 75 kilos in one year, so that his total weight before treatment commenced was 145 kilos, or 319 lbs.—nearly 23 stones.

From this it appeared that only 1,200 calories were obtained against 2,400 as a normal expression. To restore the equilibrium 1,000 calories required to be taken out of the food, either as carbohydrates or hydrocarbons, and to do this a diet of green vegetables was adopted. Within a year the body weight was reduced 60 kilos, or 132 lbs. He has more faith in the perseverance of the subject in accomplishing a cure than in any drug. The thyroid gland, he affirms, has no influence whatever on the reduction of fat. He is willing to admit that every individual case must be treated on its merits, but he assures us that he knows of no specific drug except those that are likely to produce injurious effects, such as thyroid, the action of which is to produce glycosuria, that modifies alimentation at the expense of the integrity of the kidneys.

The only effect of Oertel and Schweninger's method of fluid deprivation is to reduce the appetite, and thus check alimentary nutrition.

Banting's method with Ebstein's modification of presenting a mixed diet is certainly the most rational method of treatment for reducing fat safely.

**CINNAMON AND TUBERCULOSIS.**

Niehnes is not satisfied with the cinnamon treatment of Landerer in surgical practice. Landerer maintains that cinnamon, when injected into the venous system, produces a sort of aseptic inflammation or leucocytosis, which Niehnes is not satisfied with, but rather holds to the opinion that the cure rests entirely on the drug itself or not at all. In opening local abscesses of a tuberculous nature and dressing with heterocresol and iodoform, more good can be done than by administering cinnamic acid, and this method gives 63 per cent. of recoveries for Landerer's 90 per cent.

In the discussion Vulpis said he had tried Landerer's method in twenty cases, but the rigors and fever were so marked that he has now quite abandoned the treatment.

Niehnes thought the rise of temperature was due to the use of the cinnamon salt of soda.

### Special Article.

#### THE BRITISH CONGRESS ON TUBERCULOSIS.

##### ARTICLE II.

UNDER existing circumstances it hardly seems worth while to devote much space to certain subjects which, but for Professor Koch's startling statements, would have attracted a very great amount of attention, viz., the identification of tubercle-contaminated articles of food, the means of restricting their sale, the prevention of tuberculous disease among cattle, and the question of compensation to be paid to cattle owners for the slaughter of animals recognised to be infected. The papers dealing with these and cognate subjects were extremely numerous, but the discussions to which they gave rise lacked the conviction of opportuneness.

We may therefore pass on to the consideration of the influence of various conditions in determining a liability to infection. According to Professor Koch, heredity may be dismissed as for all practical purposes as non-existent as a source of direct infection. In affirming this truism he did but give voice to a view which has long commanded the assent of authorities in the matter. Hereditary predisposition is quite another thing, though opinions are still greatly divided as to the precise significance to be attributed to this factor in determining an exaggerated proneness to the disease. According to Dr. Squire, although some 33 per cent. of consumptives present a family history of tuberculosis, there are statistical grounds for attributing the disease to occupation and surroundings in by far the greater number, thus reducing the possible influence of heredity to 9 instead of 33 per cent. Attacking the subject from another point of view, he found that out of 469 claims under life insurance policies, 78 were from consumption and other forms of tuberculosis, and of these 78 only 7 had any history of consumption in the family, while a phthisical history was obtained in 22 cases in which death had taken place from some other cause than tuberculosis. This gives 440 cases free from consumptive taint, of whom 71 died of tuberculosis = 16.13 per cent.; and 29 cases with consumptive family history, of whom 7 died of tuberculosis = 24.13. These figures are too few, of course, to be of much value by themselves, but they are interesting as tending to confirm the opinion now very generally accepted, that the direct influence of heredity in tuberculosis is considerably less than was formerly supposed. Dr. MAXON KING, of New York, goes even further than this, for he inclines to the opinion that in many instances a certain degree of immunity is conferred upon the offspring of phthisical parents. He bases his views on 242 carefully recorded observations of tuberculosis in which he had opportunity for close personal study into the immediate family histories and such other features of the cases as would throw light upon the inquiry. Of the 103 fatal cases among this number he notes that 76 occurred among individuals of non-tuberculous parentage, the average duration of the disease in these cases from its

earliest signs to death being 2.93 years. The other 27 fatal cases occurred among individuals of tuberculous parentage in whom the average duration of the disease to a fatal issue was 4.01 years. We need not go into the details upon which he bases his conclusions, which are as follows:—1. That the percentage of consumptives having a tuberculous parentage is actually smaller than that not having a tuberculous parentage, and is much smaller than would be more than accounted for by the additional danger of infection to which the former class is subjected. 2. Tuberculosis in the parents render the offspring immune to a not inconsiderable extent, as shown by increased resistance to the progress of the disease and an increased tendency to recover among this class.

Among other factors which appear to influence the mortality from tuberculosis, Dr. VON KOSOV, of Budapest, incriminates the youthful age of the parent or parents. He found the mortality among children whose mother was under 20 to be 8.45 per cent. This proportion fell to 5.09 when the mother was between 20 and 30; to 2.78 between 30 and 35; with a rise to 4.26 when the mother was over 35. On the paternal side the mortality among the offspring of fathers under 25 was 5.71; between 25 and 30, 4.74; 3.81 between 30 and 40; with a similar rise to 6.01 per cent. when the father was between 40 and 50. These figures are not without interest in respect of the proper age for marriage.

We talk of a predisposition to tuberculosis as if it were a more or less fixed quantity, though, after all, it is merely a matter of appreciation. Dr. ALBERT ROBIN, of Paris, read a paper in which he showed that predisposition is not a mere figure of speech, but that it corresponds to certain well-defined and recognisable peculiarities of the respiratory exchanges. A study of these exchanges enables us to recognise predisposed subjects beforehand and consequently to submit them to a hygienic and therapeutic regimen capable of modifying the functional and nutritive fault which is the necessary antecedent condition for the development of the bacillus. The respiratory exchanges are found to be increased in 92 per cent. of the subjects of confirmed tuberculosis and in 63 per cent. of those with tuberculous heredity. Alcoholism and various forms of overwork increase the respiratory exchanges, and are thus capable of creating a soil for tuberculosis in the same way as heredity. From this observation he deduces a means of testing the value of treatments according to their action in modifying the respiratory exchanges.

The treatment of phthisis by climate and by "open-air" being very much in vogue, a special interest attaches to a paper by Dr. W. GORDON, of Exeter, who has studied the influence of wind *per se* on prevalence of phthisis in his part of the country. He finds that the distribution of the phthisical death-rate cannot be explained by peculiarities of soil or rainfall, sunshine or purity of atmosphere or differences of sanitation, occupation, race or intermarriage; in short, he thinks the excessive mortality in certain districts can be fully accounted for by the influence of exposure to west and south-west winds. It would appear that the influence of these winds is not due so much to their coming from any particular quarter or to any peculiarity in the matter of temperature, moisture, &c., but to the fact that the prevalence of wind leads the inhabitants to

keep their windows and doors shut night and day, thus creating a condition of non-aeration comparable to that which obtains in cities from deficient air space, overcrowding, &c. This argument is not without its importance in that it establishes the importance of choosing a sheltered spot whereon to erect sanatoria. The thing is not to exclude any particular wind, but to exclude great movements of air which make living in the open air uncomfortable. Although wind *per se* does not directly create any liability to tuberculosis, it does appear to exert an inimical action on those who are actually suffering from pulmonary tuberculosis; another reason for excluding wind from sanatorium grounds.

There remains the subject of treatment of tuberculous affections by drugs and sera, and this may be dismissed in a few words. Dr. G. A. HERON reported fairly good results following treatment by injections of Koch's tuberculin; sixteen out of fifty-seven cases having recovered. He attributed the discredit into which this method of treatment had fallen to its use in unsuitable cases and in too large doses. On the whole, he considered it as safe as any other potent drug. Professor Koch himself was much more guarded in his utterance. He stated that his tuberculin was valuable in cases of apical pneumonia, especially when influenza was suspected, also in cases of pleurisy. In early uncomplicated cases of phthisis it was, he said of great value and a complete cure frequently followed, but to obtain its maximum good effects the temperature should be normal before the injections were begun. In the discussion that followed, in which a large number of well-known authorities took part, the almost unanimous opinion was adverse to the use of this substance, and this no doubt represents the opinion of the profession at large.

The voluntary notification of cases of pulmonary tuberculosis, as set forth in a paper by Alderman McDougall, of Manchester, has much to recommend it as affording the means of ascertaining the prevalence and distribution of the disease. Its benefits, however, are not merely statistical. A knowledge of the local distribution of the disease enables the sanitary authorities to inquire into the sanitary condition of the house or district, it enables advice for preventing the spread of the disease to be given and proper sanitary precautions enjoined. Then too, the sufferer, if of the labouring classes, can be removed to a hospital or sanatorium when such are available; and, lastly, it enables the medical officer of health to insist upon adequate disinfection of the premises after death or removal of the patient. This system can only be resorted to with benefit in districts where advantage can be taken of the knowledge thus gained to carry out the consequential measures.

The infectivity of houses inhabited by the phthisical is a point upon which definite information was greatly needed. Dr. HAROLD COATES, of Manchester, brought forward some interesting observations bearing on this point. He classifies the houses with a phthisical inhabitant into dirty and comparatively clean, with a third group of very dirty houses without any tuberculous inhabitant. In twenty-three houses described as "dirty and inhabited by a consumptive patient" fourteen were found to contain infective dust, equal to 66·6

per cent. His conclusions point to the fact that while light and air are highly important, cubic space without ventilation is of no avail. Of ten houses described as "clean but inhabited by a consumptive patient," infective dust was found in 50 per cent. He concludes, therefore, that ordinary cleanliness is not sufficient to prevent the accumulation of infective material in rooms inhabited by a consumptive. The importance of lighting and ventilation was shown by the fact that in all the rooms where no infective material was found both were good. Out of ten houses described as "very dirty but in which no tuberculous disease had existed for several years," in none could any infective dust be found, so that the inference is that the virulent dust found in houses of the first two categories was derived from the consumptive persons. Incidentally he laid stress upon the importance of the thorough disinfection of dwellings which have been inhabited by the phthisical, an argument which will command ready assent.

Naturally, the provision of sanatoria came in for full consideration. It was recognised that vastly-increased accommodation is required if any impression is to be made on the prevalence of the pulmonary tuberculosis in our midst, not only for the purpose of placing the victim of the disease in an environment favourable to his restoration to health, but also, and this is not the least important, in order to remove a potent source of contamination from his family and the district. The only point calling for notice in this connection is the fact that it is unnecessary to wait until funds are provided for the construction of large sanatoria fitted with all the therapeutical luxuries of modern science. It was urged that a vast amount of benefit could be conferred by camp sanatoria—that is to say, by the provision of more or less inexpensive constructions—tents, huts, and the like. In these medical supervision would be reduced to a minimum. The great thing is that such encampments might be created all over the country with the assistance of local authorities or by private benevolence, and in view of the small cost of maintenance they might easily be made self-supporting.

## The Operating Theatres.

### THE CHELSEA HOSTITAL FOR WOMEN.

**NEPHRECTOMY AND APPENDECTOMY.**—Mr. BLAND-SUTTON operated on a woman, *æt.* 46, on account of an obscure pain in the right side of the abdomen, which was at times accompanied by a definite "swelling." The patient had during the preceding five years seen several physicians and surgeons, who had found it difficult to determine between an intermitting hydronephrosis or distension of the cæcum. Mr. Bland-Sutton, after careful observations of the patient, found it difficult to decide whether the right kidney or the vermiform appendix was the source of trouble, and determined to explore the parts through an incision in the right linea semilunaris. On exposing the parts a very long (6 ins.) vermiform appendix was seen lying parallel with and adherent to the cæcum and ascending colon. Its distended tip was in actual contact with the gall-bladder. The appendix was removed. The right kidney was completely disorganised, and its pelvis with the adjacent segment of the ureter was dilated into a large sac. On careful examination he assured himself that it would be

judicious to remove this troublesome organ, especially as the left kidney appeared to be sound and efficient. Nephrectomy was carried out without any difficulty, the large flaccid renal pelvis being carefully dissociated from the vessels before they were ligatured. The abdominal incision was sutured in three layers and without drainage. Mr. Bland-Sutton observed that the case was of interest because pains in the right side of the abdomen accompanied by a swelling, permanent or temporary, were often puzzling. Thus a gall-bladder might be so distended with pus, and reach so low as to simulate an appendix abscess, and he had evacuated an abscess, of which the gall-bladder formed part of its wall as high as the right costal arch, which contained the detached tip of the appendix. He pointed out that an ovarian abscess or a distended Fallopian tube adherent to cæcum simulated appendix trouble so closely that the distinction was only possible on actual inspection. Further, it was often extremely difficult, he said, to diagnose an acutely inflamed and distended gall-bladder from an acute hydronephrosis, or a chronically inflamed gall-bladder from a movable kidney. In doubtful conditions it was, he thought, always wise to carefully inspect the swelling through an incision in the abdominal wall, and then act according to the organ which is the source of trouble: it may be colon, cæcum, or appendix, kidney, liver, gall-bladder, or perchance the pylorus. Often it is the ovary or Fallopian tube.

The patient made an uninterrupted recovery.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 7, 1901.

### THE WORK OF THE METROPOLITAN ASYLUMS BOARD.

THE Annual Report of the Metropolitan Asylums Board furnishes an interesting account of the progressive administration of various Poor-law and municipal institutions. As a record of vigorous and enlightened administration it is of value to local bodies in all parts of the United Kingdom, and, for that matter, of the whole of our world-wide empire. The work of the Board is multifarious and important

including, as it did, for the year 1900, the care of 5,727 imbeciles, of 5,180 fever patients, of 1,492 small-pox patients, and of 860 children in homes, or a grand total of 13,266 persons at a cost of £832,465. One of the most arduous additional duties consists in the conveyance of 33,791 infectious patients to and from hospital. This branch of the administration involves a large staff of servants, and its services are available daily throughout the year. Some idea of the magnitude of its operations may be gathered from the fact that during the year the ambulances of the various stations covered in all a distance of 232,848 miles. There are also three ambulance steamboats and an ambulance steam launch in working order, and these together have conveyed 1,635 patients, and covered a distance of 4,757 miles. It is interesting to note the growing popularity of the infectious hospitals, which are open to any persons irrespective of their social position. In this connection the Report states that the increasing use of these institutions by the public has been one of the reasons that have compelled the Board from time to time to extend their building operations. But there are other causes at work, namely, the additional accommodation required by imbeciles, and the increase in the various classes of poor children entrusted to the care of the Board. With regard to the latter point it is a matter of some surprise that a public body with practically unlimited funds at disposal should be obliged to record another year's delay in carrying out the provisions of Mr. Chaplin's famous Departmental Order. The task of finding accommodation for the five classes of Poor-law children was handed over to the Asylums Board. The specified classes fell under ophthalmia, ringworm, convalescent, and mentally defective and remand children. The present position may be summed up in the statement that neither ophthalmic nor ringworm children are yet received, although accommodation has been provided for 160 of the latter class, a mere fraction of the total number thus affected. Homes have been founded at Herne Bay and at Margate for convalescents. Some slender accommodation has been provided for this defective class, but none at present has been obtained in the case of children under remand from the police courts. After making every allowance for the legal and other difficulties of the situation the Asylums Board can hardly be said to have risen to the present occasion with their usual energy and thoroughness. During several years they have been enabled to deal with Poor-law ophthalmic patients only by availing themselves of that most excellent pioneer institution, the ophthalmic isolation schools at Hanwell. The Board have secured two sites for children suffering from ophthalmia, namely, at Brentwood, in Essex, and at Swanley, in Kent. The total cost of those institutions will be very great, but economy has never been a strong point with the Asylums Board. However, the money thus spent will not be grudged by the patient ratepayer, provided it be shown that he

obtains in return accommodation of ample dimensions and first-rate quality. £832,465 18s. 5d. is a large sum to pay for the various purposes of the Board, but it is a relatively small sum if regarded in the light of an insurance premium paid for the protection of the public as far as may be against the costly inroads of infectious disease. In the course of time it may confidently be hoped that preventive medicine, of which the Asylums Board is a faithful and powerful handmaid, may extend control over the additional scourges of measles and whooping-cough. In that event the Board will be called upon to make fresh efforts, although it may reasonably be expected that some of the diseases which now tax their energies may have notably diminished. Everyone interested in the problems of modern social life will do well to study carefully the admirable Report of the Metropolitan Asylums Board for the year 1900.

#### "LATENT" FRACTURE OF THE SPINE.

MUCH comment has been aroused in medical circles in Dublin concerning the sudden death of a pharmaceutical chemist, which took place on July 20th. It would appear from the account in the public press of the evidence given at the inquest held on July 22nd, that the deceased told his assistant, when the latter arrived at the shop at about nine o'clock on the morning of July 19th, that he had fallen down the cellar stairs. He complained of having hurt his ankle, but otherwise appeared to be in good health. About an hour afterwards he got on his bicycle to ride to the Meath Hospital Dispensary, and this he seems to have been able to do without much distress. He returned to the shop at one o'clock, and attended to business there until about half-past two o'clock, complaining only of his ankle. A second witness who saw him at this hour corroborated this account. A third witness who had called at the shop at three o'clock to get a prescription compounded, deposed that the deceased complained to him of having fallen downstairs and dislocated his ankle, and said that he had telephoned for a doctor but could not get one. The witness offered to take him in his trap to a doctor. The deceased hopped on one foot to the trap, which he entered without assistance. The witness subsequently returned with him to the shop, and, during the whole time he was with him, he had no reason to suppose that he suffered from any other injury than an injured ankle. Later another doctor saw him, and ordered a lotion which contained opium to be applied to his ankle. The deceased chemist's brother saw him in the evening just after this doctor's visit, and found him lying in his clothes on his bed. He complained of pain but without specifying where he felt it till he attempted to remove something from the pocket of his brother's trousers when he made complaint of pain in his back. The deceased asked him to walk quietly in the room as the least vibration hurt him. The deceased appears to have been alone from about

eight o'clock in the evening until eleven when his brother returned and remained with him. The deceased was alive at about 2.30 a.m. on the 20th ult., but when his brother awoke at 7 a.m. he was found to be dead. At the post-mortem examination performed by the last doctor who saw him alive, a second doctor being present, the posterior cervical region was carefully examined in consequence of a large extravasation being noticed in that region, and a fracture of the left articular process of the fourth cervical vertebra was found with extra-dural effusion. The spinal cord does not, however, appear to have showed signs of gross laceration or compression. The brain was examined, but nothing else was found to account for death. The analyses of the contents of the stomach failed to show that the deceased had swallowed any of the lotion, as was apparently suggested. It appears from the evidence that the unfortunate man not only attended actively to his business after the fall which injured his ankle and, it must be assumed, fractured the spinal articular process, but even rode his bicycle, and hopped to and from a trap without complaining of pain in his neck or back. The doctor, to see whom he was driven, was not called at the inquest, nor was evidence taken from those who were on duty at the hospital. That a man may walk about almost immediately after having sustained a fracture of the upper cervical vertebræ, and resume manual labour after a few days, has long been recognised, but it nevertheless must strike one who judges the case from the report of the evidence published in the public press as extraordinary, that, with such a lesion as was found post-mortem, pain in the region should be so little complained of, and that the movements of the neck should be so free that though several skilled medical men and others saw the patient their attention does not seem to have been called to his neck. It seems hard to understand why death should have taken place unexpectedly, even supposing that the roots of the phrenic nerve "were so compressed by extravasated blood that it ceased to carry on its functions," one would expect that its fellow would have done duty sufficiently long to allow warning of impending danger. The cord itself was apparently found to be compressed by the hæmorrhage or fragment of bone. Paralysis of the diaphragm alone can be but very rarely a cause of such sudden and unexpected death. The coroner was perfectly justified in his selection of the medical attendant—whose ability no one will question—to perform the post-mortem examination. At the same time it would perhaps have been more satisfactory if, instead of the parts removed being brought (as was done) to a skilled pathologist, the pathologist had been brought to the post-mortem examination in the first instance. We are far from intending to infer that the examination was not satisfactorily performed; the known and acknowledged ability of the gentleman who performed it is a sufficient guarantee that it was, even had he not had a second medical man present during

its progress who corroborated his evidence. It is to be hoped that an authorised report of this extremely important and interesting case will be published in detail, as it would seem to fall under the head of the rare condition known as a "latent" fracture of the spine—a name given years ago to such cases by Simon.

#### SCIENTIFIC EDUCATION.

THE President's Inaugural Address at the Cheltenham meeting of the British Medical Association had many features of interest, notably the learned and attractively written historical retrospect. On this alone we might comment at some length. But we refrain from doing so in order to throw into stronger relief a matter of equal interest and even greater importance, the plea, namely, for better and more widely-diffused scientific education in our land. Dr. Ferguson dwelt on the striking fact that many of our most far-reaching discoveries in connection with the healing art had been the work, not of the men in the actual practice of the profession, but of pure scientists, both biologists and chemists. True, had he chosen to illustrate the value of the work of practical medical men, he could have found examples sufficient; but let that pass. For the present we may follow the President's line of argument; the deduction from his theme was the value of a pure scientific education, and he found opportunity for making some most important corollaries on the subject. He somewhat mournfully pointed out that the want of scientific technical education was driving out much manufacture from this country; taking as an example the aniline dyes, he reminded his hearers that while the discovery of these dyes was the work of an Englishman, the process of their manufacture now practically lay in the hands of a German firm, employing hundreds of analytical chemists, and thousands of workmen. He uttered a warning that has been uttered before, and that may require frequent repetition before we as a nation take it to heart, that an extension of this principle will mean untold financial loss to this country. And the loss will be all the greater because it is not only a question of a present pecuniary disadvantage; the worst feature of the business is that the mental capacity, ingenuity, and resources of our young men are not being exercised, and consequently we must necessarily get left further and further behind in the great world-competition. Dr. Ferguson warmly contended that a country which had produced the epoch-making discoverers of the last century was not barren either of genius or of industry; but our sons must have a fair chance, they must not be hopelessly handicapped. The moral and the remedy are clear, nor did the orator fail to point the one and define the other. We must have more scientific and technical training at our universities, available not for the few but for all; we must insist that the work of a university is not primarily to examine, but to teach; and not only to teach, but principally to train up the students to investigation and research, and to bring

out and develop all their faculties of thinking for themselves. In a word, they must be taught to use and apply as well as to acquire knowledge. Schools of engineering, of applied chemistry, of technical industries, of biological research, must be multiplied and endowed. Naturally we look first to the State, but the State, like Jerusalem of old, is slow to perceive the things that make for her good, and slower still to act on these perceptions when they are acquired. Failing the State, we must look to the public-spiritedness and the generosity of our wealthy men. Fortunately there are not wanting signs that the hour will bring forth the man; the recent munificent gifts to the Scotch universities are fresh in our memories. But must we long wait for the fulfilment of the aspiration that the Twentieth Century will see the establishment in every great city in our land of a true university, well-endowed and amply provisioned for thorough training in all those branches of pure and applied science on the development of which commercial and social prosperity depends? For these things did the great Huxley labour and contend. May that mighty force, a nation's conscience, soon awake to insist on their fulfilment!

#### Notes on Current Topics.

##### Signal Success of the Revolt Against "the Flannery Clauses."

It is with unalloyed satisfaction that we announce to our readers to-day the complete success of the indignant revolt of members of the profession, headed by the Bradford and West Riding Medical Union, against the oppressive, insulting, and heartless duties which Sir Fortescue Flannery, M.P., proposed to inflict on them by obligatory penal clauses in the Factory Bill now before the House of Commons. We gladly gave our support to the movement in opposition to those clauses, and in our issue of July 17th condemned them root and branch. The success of our opposition has been complete; Sir Fortescue Flannery has unreservedly withdrawn his indefensible proposals, and we are undisputably victorious. Such a rapid success was hardly to be anticipated. One naturally supposed that Sir Fortescue Flannery would not have dared to propose such an unparalleled amendment attacking alike the sacred privilege of a dying patient and his friends, and the rights and duties of the medical attendant, unless he had fortified himself with what he regarded as incontrovertible arguments in his favour, and we supposed he would have fought hard to defend his cause. But we did him wrong in this. Having proposed to inflict unjustifiable indignities on the profession, and to make the sick room the scene where the doctor would have to struggle with patient and friends to secure a sample of the patient's blood, Sir Fortescue has proved by his sudden surrender that he feels he had no justification whatever for his proposals. The absurd and unworkable character of the wording of his clauses is in itself proof of how lightly he regarded

the seriousness of what he was attempting. He is probably to-day a wiser and a sadder man. Had he not surrendered unconditionally the opposition would have resisted him to the bitter end, and every form of the House of Commons would have been employed against him, even to the last resource of destroying the whole Bill. This uncompromising attitude is the only one which need ever be adopted if success is wished for, in resisting such nefarious attempts. For the profession has unfortunately allowed itself to become a bye-word for want of power of resistance and apathy. Hence the increasing number of penal enactments to compel medical men to render obligatory services to the State. They alone, of all subjects of this realm are forced, to give to the public, by Act of Parliament, the fruits of their study and experience. To them alone has Parliament dared to say, "The fruits of your toil shall not be your own, you shall render them to others, who have no right or title to them, except that those fruits are valuable and very useful." THE MEDICAL PRESS AND CIRCULAR has always upheld the rights of the profession, and of all the medical journals in the country it alone has entered the lists against the Flannery clauses. It is with supreme satisfaction we record the fact and the victorious result. This notable success is another illustration of how great is the power which the medical profession possesses if it will only rouse itself to promote its own interests. THE MEDICAL PRESS AND CIRCULAR is always ready to support these interests, which form the object of its existence. Never have our columns been closed through self-interests to the greater claims of the noble profession whose organ we are. We cannot conclude without drawing the attention of the profession to the great debt which is due to the Bradford and West Riding Medical Union for its splendid service in the matter, and in particular to its President, Dr. Goyder, and to Dr. Hime, who have done yeomen's service. It is not the first time Bradford men have won notable victories for the profession, exhibiting an example of unity, energy, and success which is an object lesson to the country. This contest has not been a local one in defence of Bradford interests. The Flannery clauses trampled on the rights of every medical man in the country.

#### The Lady Doctors' Opportunity.

OWING to the absence at the front of so many young surgeons there is a striking difficulty in obtaining candidates for resident posts in hospitals and public dispensaries, especially in the provinces. So much is this the case that in quite a number of instances the only candidates have been qualified women, and they have accordingly been appointed. A contemporary points out that if the present dearth of candidates for the Services continues the Government may seriously have to consider the propriety of employing female labour. The authorities have a rooted objection to the employment of women, as evidenced by their obstinacy in withholding a supply of nurses at the front until public opinion became too

strong for them. We doubt, however, whether public opinion would view with complacency an innovation in this direction, and the British soldier, who at heart is a modest being, would probably resent being obliged to unfold his tale of woe to an adviser of the opposite sex. One of the most distressing consequences of the dearth of unattached medical men is the difficulty with which practitioners, desirous of enjoying their well-earned repose, find in providing substitutes. As *locum tenens*, the lady doctor presents certain incontestable advantages. She is sober, assiduous, and socially trustworthy. Nothing is farther from our idea than to insinuate that the male *locum tenens* is the reverse of this, but it is notorious that a certain proportion of the gentlemen who are willing to serve as substitutes present drawbacks of a more or less serious kind. Still the moment has not yet arrived when the average practitioner could safely entrust his *clientele* to the safe keeping of a lady substitute be she never so well suited for the post.

#### The Mechanical Side of Surgery.

WE are constantly being reminded that there are a great many things which the ever busy student is not taught. A surgeon, inspired no doubt by the fact that he resides in Toledo (Ohio), complains that students are not taught how to sharpen their scalpels. Now it is a matter of fact that a very large proportion of surgeons would further impair the cutting edge of a knife if they tried to confer upon it the indispensable sharpness. This consideration prompts the author to lay it down that no person should be allowed to practise surgery without first learning a mechanical trade. No doubt manual dexterity, however acquired, is a precious quality in every walk of life, but in deference to the principle of the division of labour we have allowed ourselves to fall into the habit of delegating these details to the surgical instrument maker. The important points to be remembered in "boning" a knife, it appears, are to pull it along the stone from heel to point with the cutting edge forward at an angle of about 45 degrees. When "stropping" a knife, on the contrary, it should be drawn from heel to point *away* from the cutting edge. If this information should be the means of obviating the necessity of any of our readers taking out a course in a workshop we shall have earned their thanks.

#### The Difficulties of Medicine.

THE address in medicine which Dr. J. F. Goodhart delivered at the annual meeting of the British Medical Association at Cheltenham is characterised by a Montaigne-like chattiness which made it pleasant to listen to in spite of its genially cynical tone. Dr. Goodhart had no pet theme to discuss, and apparently no particular moral to enforce, but he delivered himself of a series of more or less discursive remarks on medicine as it is practised, which must have convinced his audience that "the best of us are but gropers in the dark," though "any

fool can give a name to a disease." Fortunately Dr. Goodhart regards the prevailing ignorance with philosophical indulgence, he does not twit us with knowing so little, all he asks apparently is that, knowing so little, we should not pretend to know so much. He even goes so far as to palliate our shortcomings in view of the difficulties which hem in research on every hand. We have heard a good deal of late, he observed, about water tube boilers, their intricacy of working and their excessive wear and tear, and the difficulty of their repair without stopping the ship. What, he asks, would be the position of the engineer if such a vessel could be worked automatically with the hatches down, positive knowledge of the condition of its entrails being obtainable only by the observation and analysis of the smoke and bilge water, by post-mortem examination at the breaking up of old vessels and the recording where each had gone to pieces? Yet that is the position of the medical practitioner when he attempts to modify or control function. Fortunately the animal organism has the advantage over the vessel of a certain self-righting power, but this again is an unknown quantity, and not even the wisest among us can foretell with any approach to certainty whether in a given case the disturbance is one the remedy of which it is within the power of the organism to compass.

#### Let the Hire be Worthy of the Labourer.

ONE reason why the public as a rule set so little store by medical advice is that medical men weakly allow themselves to be cajoled into perpetuating the popular belief, the product of the thought which is child to the wish, that for every disease there is an appropriate remedy. None better than the medical practitioner knows that in the vast majority of cases which come under his notice it is advice and not medicine which is needed, yet the courage fails him to declare the fact and to act on it. This may, as suggested by Dr. Goodhart in his address at Cheltenham, be one reason why people accept and pay for advice from lawyers readily enough while they fail to appreciate medical advice pure and simple. Advice, he exclaimed, just think of it! A product of so unique a value, that when a man of great experience in the world of medicine dies his knowledge dies with him; no other man can supply his place, and there is a dead loss to the community of a mine of unrealised information. Referring to a very very clever signboard in which a bullock is seen gazing yearningly upon a small jar of meat extract and exclaiming "Alas! my brother," he said he wished he could pot brothers as they flitted from off the stage; his trouble was that his great masters died unbottled. And yet we "give" advice, and there are those in number who not only accept but ask the gift. And this advice, it has been asserted, is dispensed upon the strictest trades union principles which have been defined as "doing the worst possible work at the highest possible price." Why, it is

notorious that such is the generosity of medicine that there is not a needy person in the whole kingdom who cannot, if he need it, obtain the best opinion in the country gratuitously. The clergy, the army, the navy, artists, actors, actresses, clerks, artisans, and others, pour into a doctor's room or the hospital asking alms in the shape of advice and never get a refusal. And after it all we are insulted by being called trades unionists—"men who do the worst possible work at the highest possible price!" Verily we have ourselves to thank for this in great measure, for we belittle the value of our advice in allowing the public to exalt so greatly the supremacy of mere physic. The labourer is worthy of his hire is but one side of the question, and not the best side; for it might be held to cover many a sordid act; the other and much the more important is surely this, "See to it that the hire is worthy of the labourer," in the form of the higher and nobler recompense of dignity and self-respect.

#### Phthisis at Bordeaux.

THE town of Bordeaux has instituted an excellent method of practically dealing with the cases of tuberculosis within its boundaries. An Anti-Tuberculous Society has been formed that publishes documents relating to tuberculosis, encourages the use of tuberculin in the stables from which milk is supplied, assists the doctors by analysing and reporting on sputum or other specimens in suspected cases; when necessary, carries out inoculation experiments in guinea-pigs for the purposes of diagnosis, and in every other way possible furnishes aid to the physicians concerned. We are glad to hear that the latest reports speak in the highest terms of the success of this very sensible means of combating the ravages of phthisis.

#### The Proposed Cancer Congress.

WITH a great many people the panacea for ignorance in any subject is a congress, or at any rate a commission of inquiry. They attribute to these bodies sundry occult powers of discovering the truth, and, having voted in favour thereof, they fold their hands in the blissful consciousness of having done something to help the cause. Scientific men on the contrary are disposed to question the gain to knowledge of these ever-recurring congresses. It is difficult to define in these days of international journalism the way in which these gatherings can advance our knowledge of the subjects under discussion. If anything new or interesting crops up which is quite exceptional, it simply means that a particular investigator has held over his communication in view of the meeting. Truths are not elucidated in view of a congress, and failing such a meeting they would be communicated to the scientific world by the ordinary channels, which, after all, are better suited to the purpose. Of all subjects in the world in respect of which a congress would be futile and indeed absurd, cancer is the least amenable to discussion. What we require is fact not discussion, and facts are being

strenuously sought after by hundreds of trained intelligences throughout the civilised world. No stimulus is needed in the way of prizes or rewards, the privilege of having been able to throw light on this dark corner in pathology would be, in itself, ample compensation for a lifetime devoted to laborious research. The endowment of research is another matter. The labourer cannot give the measure of his skill without the proper tools, and men who devote their time and energy to unremunerative pursuits must be provided with the means of subsistence.

#### Resuscitation in Chloroform Narcosis.

ANY amateur anæsthetist who has been suddenly called upon to "do something" in an alarming case of chloroform narcosis must wonder how it was that he could think of so few measures when so many have been suggested. Some of them, quoting from a recent article by Dr. A. Wilson in the *New York Medical Chronicle*, might not occur to the average practitioner. We note, for instance, the application of Corrigan's button to the epigastrium, dilatation of the sphincter ani, or the application of a hot sponge to the perinæum. Should none of these occur to the person in charge of the case he may stimulate the heart by intermittent pressure, rapid percussion, faradisation, or acupuncture. Failing the presence of mind to carry out all or any of these restorative procedures the belated physician may advantageously administer, subcutaneously or by inhalation, always supposing that the patient will breathe for the purpose, drugs which have the power of stimulating the depressed nerve centres—ammonia, nicotine, strychnine, extract of suprarenal capsules, "and the like." It is hardly conceivable that he should be unprovided with these everyday drugs, or that he should forget or omit to make use of them. Seriously, however, of all the measures suggested for the resuscitation of the apparently narcotised, the only ones likely to prove of instant avail are the head-low position, artificial respiration aided by rhythmical traction on the tongue, and percussion over the cardiac area.

#### Popular Theories of Tuberculosis Prevention.

FOR the time being the daily newspapers contain many "letters from correspondents" desirous of airing their views of how to prevent the spread of phthisis. In ninety-nine cases out of a hundred their arguments are rendered worthless by some plan that would be evident to anyone possessing a modicum of medical training. This persistent effort to solve problems that have hitherto defied the most advanced medical skill is not without its underlying moral. It shows, for one thing, how the average man prefers to trust his own judgment in matters of medicine, notwithstanding the particular point on which he elects to give his decision involves a knowledge of facts in prevention, causation, and treatment of an insidious malady, to say nothing of a close acquaintance with pathology, bacteriology, chemistry,

and other subsidiary branches of medicine. In many cases the intelligent layman not only feels himself capable of cutting the Gordian knot, but also of deciding which quack remedy of unknown composition he will purchase by way of cure. Instances of this species of misguided sagacity on the part of *the man* in the street are "plenty as blackberries" (*sic*). Last week a London daily newspaper contained the sapient suggestion that all tuberculous sputum could be rendered harmless if pellets of creosote and eucalyptus were kept in the patient's mouth. In other words, he would trust the destruction of the myriads of bacilli buried in the sputum to their momentary exposure in the mouth to a feeble disinfectant surface. Some day it is to be hoped that the newspapers generally will be educated in the rudiments of preventive medical science.

#### Malaria and House Sanitation.

THE ancient sanitary maxim which directs every man to "keep his house in order" has received a fresh and striking illustration in the case of malaria. In an interesting letter addressed to the Honorary Secretary of the Liverpool School of Medicine, Major Ronald Ross has described the steps taken to rid Freetown, Sierra Leone, of the mosquitoes that carry malaria. The main attack has been naturally directed against the pools of water in the district, for those sites, as most folk know nowadays, are the natural breeding places of the pestiferous insects in question. A most important additional portion of Major Ross' work, however, has been devoted to the houses of the town. He has organised a gang of seven men, who are constantly engaged in destroying mosquito larvæ in private houses, and in carrying away tin cans, broken bottles, old buckets, and other receptacles in which these dangerous little midges breed. They clear about forty houses daily, and carry off in that way some ten cartloads of pots, of which about one-third formerly bred mosquitoes. This pen and ink sketch presents a most instructive object lesson of practical sanitation founded upon advanced scientific discovery. It emphasises afresh the old observation that tropical disease is often favoured by the bad sanitary environment of the dwelling-house. A few years ago the average intelligent European would have laughed the laugh of the scornful had one told him he was fostering malaria by throwing his empty pickle bottles and meat cans on the domestic dust heap. Yet nowadays science has demonstrated the relationship of those apparently absolutely diverse facts.

#### The Housing of the Poor.

MR. FLOWER, one of the speakers in the recent debate in the Commons upon the Local Government Board vote, appears to entertain an exalted idea of the capabilities of that Department. He suggested that the Board should instruct the local authorities in the building of houses for the very poorest at such a cost that the rentals would come within the means of the class for whom the houses were intended. His theory of the relations that should

exist between the central and local administrations in this important particular is almost ideal. Unfortunately, in attempting to reduce his views to practice he would find himself faced with some very hard nuts to crack. Many experiments have been made by public bodies in various parts of the United Kingdom to erect cheap artisans' dwellings. Hitherto, however, the plainest buildings and the cheapest materials have cost so much that it has been found impossible by means of a small rent to pay interest on capital and repay original capital by a sinking fund. The only two factors that are really capable of reduction are the extension of the time for repayment of prime expenditure and the high price of land. To deal with those underlying causes is clearly in the hands of Parliament, and not of local governing bodies. The attention of Mr. Flower may be drawn to these elementary considerations, in order that he may consider the advisability of going to the fountain head for his most desirable reform. It is, of course, within the bounds of possibility that he may have evolved some practical solution of the housing problem. In that case his scheme would be of advantage to the Local Government Board, which cannot be expected to play the part of blind leader to blind local bodies.

**The President's Address at the British Pharmaceutical Conference.**

As might have been expected, the President's Address at the Dublin meeting dealt with the advance of sciences collateral to pharmacy during the century. To do any justice to the address in an article is impossible, for to get an idea of its great range of subject, its fulness of information, and the learned orator's mastery of his subject, the address must be read. The first thing that strikes the reader is the fulness of details and their natural arrangement, fact follows fact naturally and smoothly, so that the reader glides along a century's history without one jarring note. Passing over the earlier passages we come to his story of the progress of dentistry, in which good work British workers bore no small part. Davy, Dacton, Crookes, Ramsay, Dewar, Kelvin, Brown, figure as fellow-workers in the world of science, with Reozelius, Meyer, Mendcalf, Pasteur, Coventon, Pelletier, and others. In this connection we are sorry that Kane, O'Donovan, and O'Shaughnessy are not mentioned. Kane was, perhaps, the very first to demonstrate that the hydrogen of ammonia was displaceable, O'Donovan's papers on aloes were among the first detailed accounts of the analytical searches for alkaloids, and O'Shaughnessy's researches on Indian drugs have a permanent value. Dewar's experiments unfortunately failed to recall those of Andrews on the allotropic forms of oxygen. We merely mention these; in no carping criticism do we judge of the brilliant address. To Liebeg he ascribes the discovery of chloroform. We are inclined to think that the discovery was due to Washington's friend, Mr. Samuel Guthrie, chemist, to the Army of Independence. It is, however, merely a question of priority, for the anæsthetic was inde-

pendently discovered by Guthrie, Liebeg, and Soubeiran. Botany claimed a large share of the President's attention, and he pays a well deserved compliment to Dr. D. Moore's "Cybele Hibernica," which has done so much for Irish flour. He refers, among others, to Bentley and Trimen's praiseworthy "Medicinal Plants," and yet we regret there is no reference to Dr. William Woodville's "Medical Botany," though it was published as early as 1790. Yet it for beauty of illustration and accuracy of delineation still remains *facile princeps*. The more modern study of bacteriology in its early history, its present development, and its fascinating story, for the speaker has the gift of clothing the dry bones and giving them form, life, and beauty, so that the fascination of genius robs the brain of weariness, and as subject follows subject the listener feels no fatigue, and his receptivity of the story of scientific progress remains undulled. The address is a great one, worthy of the man and of the occasion.

**Increase of Lunacy in the Yorkshire District.**

THE increase of lunacy is unfortunately being reverted to much too often in our columns, and for reasons which are unavoidable, and which are frequently spoken of. Three main groups of the insane are now and again coming up for notice—paying patients, epileptics, and idiots. No sooner is relief granted in one direction than it is claimed in another. The discussions which arise at the meetings of our Committees on the subject of lunacy and allied social and medical matters, are very interesting, especially when well reported in local newspapers, and useful in furnishing an education of the trend of public opinion on the subject of the value given to these matters. If the camera of the reporter may be really taken as a correct one, we should say that the most clamorous views, *it may be also the coarsest*, are those of the epileptics and the idiots, perhaps because they are most repulsive. One thing is certain, a good deal has yet to be done, however before our duty has been accomplished towards the miserable people who are able to do so little for themselves.

**Modern Casualty-Room Work.**

NOWADAYS the work of the hospital casualty-room has become more or less modified in accordance with the trend of modern aseptic surgery. Personal cleanliness is rightly regarded as a matter of first importance among dressers and house surgeons; thus, the dresser is directed to wash and to disinfect his hands before dealing with any injury that either involves operation or presents a breach of skin surface. The patient's skin is most systematically and carefully disinfected. Instruments are boiled from time to time and kept in antiseptic solutions, of which the one in forty carbolic lotion still remains a chief favourite. Sutures are of the non-absorbent and aseptic type, such as catgut, silkworm, gut, and horsehair, kept ready in jars of antiseptic lotion. A handy general dressing is gauze

kept in carbolic lotion and wrung out before use. Burns are cleansed with boracic in preference to carbolic lotion, as the latter is painful and liable to absorption. Boracic acid lotion is also used almost exclusively for the eye and face. The ointments in vogue are chiefly boracic acid, yellow oxide of mercury, and eucalyptus and vaseline, or other antiseptic unguents. Large quantities of boracic acid powder and iodoform are applied to wounds, while bruises are treated with glycerine and belladonna on lint. Poultices have been entirely superseded by light antiseptic fomentations applied under oiled silk. The results of modern casualty-room work are most encouraging, as rapid healing is the rule, and septic complications are extremely rare.

#### Disinfection after Cancer.

THE recent public allusion of the King to cancer and its possible prevention cannot fail to attract widespread attention to the subject. Indeed, it appears to have already roused the energies of the Eton Rural District Council, as testified in their proceedings last week. One of the members went so far as to ask the Medical Officer of Health if he disinfected after cancer. The official in question replied that in a report he was preparing on cancer he proposed to recommend that houses should be cleansed properly at his discretion. This proposal, it need hardly be remarked, registers an extremely high standard of preventive health administration. Indeed it may almost be regarded, in the absence of absolute proof as to the infectiveness of cancer, as somewhat transcendental in character. On the other hand, the Eton Rural Council may be asked whether they have adopted systematic disinfection in tuberculous disease which is known to be due to a specific bacillus. Then, again, there are the familiar scourges of measles and whooping-cough, which probably kill a far greater number than cancer of the inhabitants of the twenty parishes that make up the Eton rural jurisdiction. Perhaps one day the prevention of the two humbler maladies may become fashionable, and the desirability of disinfection after their occurrence be more widely recognised by the local authorities of the United Kingdom.

#### Save me from my Friends!

SOME ill-advised person has written a letter to *The Times*, to which it is to be regretted that the editor gave publicity, complaining that a paper by Dr. Maguire, of the Brompton Hospital, was "relegated to an obscure position" at the Congress on Tuberculosis, and virtually ignored. The writer signs himself "A Layman," and with a truly layman's confidence he claims that the treatment by Dr. Maguire's method has produced marvellous results in cases "regarded as hopeless," and he is correspondingly indignant at "this virtual suppression." We feel sure that no one deplors this tactless effusion more than Dr. Maguire himself, the more so as any suggestion of his, supported by encouraging results, would certainly receive respectful attention at the hands of his brethren.

#### A Judicious Forecast.

THE London correspondent of the *New York Medical News* may be congratulated upon the possession of an unusual degree of perspicacity. In the issue for July 13th he observed, in reference to Professor Koch: "It may be said of him, as it was said of Dupuytren, that his motto might be '*Faire autrement*.' He has, as far as so godlike a man can share in human weakness, the instinct of sensationalism, and from the somewhat mysterious foreshadowing of the lines of his address which he has communicated to the officials, one may gather that he intends to say something that will startle the Congress." This the Professor has certainly done, not altogether to the satisfaction of the scientific world, many members of which have reached an age at which sudden and violent emotions are disagreeable and even dangerous.

#### First Egyptian Congress of Medicine.

WE are asked to announce that the first Egyptian Congress of Medicine will be held at Cairo between December 10th and 14th, 1902, under the patronage of His Highness the Khedive and the Government of Egypt. Contributions are invited more particularly on diseases peculiar to that country, such as bilharzia, ankylostoma, bilious fever, hepatic abscess, &c. Epidemiology will necessarily afford an important subject of discussion. The complete programme will be published later, when particulars will be given of facilities of travel accorded by the various companies.

#### The X-Rays and Malingering.

AN unfortunate man who has been obliged to undergo the anxiety and suspense of three trials spread over the period of thirty-six months for what is in Russia the criminal offence of malingering has at last succeeded in convincing the authorities that he is not the arch impostor it was sought to prove. The man came under examination as an Army recruit and was found to exhibit a swollen left ankle and foot. He said he had received a blow from a heavy weight upon the foot. The military surgeons accused him of malingering, and averred that the œdema had been induced by bandaging. At two different trials he was sentenced to imprisonment, but at the third trial a skiagram proved that there had been a fracture from the blow affecting the tarsal arch, and injuring the circulation in the part concerned. An earlier resort to such a very obvious diagnostic method would have spared the wretched patient many months of misery.

#### PERSONAL.

MR. THOMAS JOHN CARSON, L.F.P.S. and L.M. Glasg. has been placed on the Commission of the Peace to the Borough of Oldham.

PROF. W. E. SMITH has resigned the post of Medical Officer to the London School Board which he has held for the past twelve years.

THE King has been pleased to appoint Dr. William Hoffmeister and Dr. Edgar Hoffmeister medical attendants to the Royal establishment at Osborne.

THE death is announced of Dr. Widerhofer, the Austrian Court physician, whose name is perhaps best known in connection with the tragic death of the late Crown Prince Rudolf.

THE Gilfillan prize has been gained by a lady for the first time, and was awarded last week at the Edinburgh University Graduation Ceremony to Miss Agnes Moore Hamilton, M.B., B.Ch. A full list of prize winners and gold medalists will be found in another column.

THE Chesterfield Medal for Dermatology, given under certain conditions as the result of a competitive examination at St. John's Hospital for Diseases of the Skin, has this year been awarded to George Norman Meachen, M.B., B.S.Lond., M.E.C.P.Edin., M.E.C.S., Clinical Assistant to the Hospital for Diseases of the Skin, Blackfriars.

SURGEON-MAJOR-GENERAL W. A. THOMSON, M.B., Hon. Phys. to the King, has been selected for a Good Service Pension. It is nearly fifty years since this officer received his first Commission as an Army Surgeon. He has served in many parts of the world, and at the time of his retirement in 1892 he was Principal Medical Officer in India.

## The British Medical Association.

### ANNUAL MEETING HELD AT CHELTENHAM,

JULY 30TH TO AUGUST 3RD, 1901.

Few pleasanter or more suitable places for the meeting of a Congress whose votaries seek to combine work and pleasure could be found than Cheltenham. A fair town, situated in the midst of lovely surroundings, it has, in the first place, the charm of historic associations. Here rank and beauty have foregathered. Beau Brummel walked its streets, crowned heads have drunk its waters. Nor can the medical profession ever forget that one of the greatest of its members here led a humble and useful life—Edward Jenner. The British Medical Association met here once before, and it is a coincidence of special interest, as the Mayor of Cheltenham remarked when welcoming us to the town, that as this meeting takes place in the year of the accession of our gracious King Edward VII., so the last meeting was in the year of accession of his illustrious predecessor, Victoria, the great and good. Then the Association was in its infancy, and its members barely reached four figures; now with a membership of nearly 19,000, its branches are found all over the British Empire, and it has become a power in the land. The inaugural meeting derived a special interest from the presence of delegates from nearly all parts of the British possessions; and as they stepped up on to the platform to shake hands with the President, they were loudly cheered. Of the President, Dr. G. B. Ferguson, we may say that seldom has a more genial, eloquent, or learned President occupied the chair; and his masterly address will live in the memory of probably every one of the large gathering privileged to hear it.

The Mayor and Mayoress of Cheltenham deserve a special word of tribute to the hospitality which they showed, and in which they were cordially supported by the Town Council. They accepted the visit of the Association as an honour, and in so doing conferred an honour on their guests.

#### ENTERTAINMENTS.

These began with a largely-attended "At Home" on Monday evening at the Winter Garden, where the Annual Museum and Exhibition were held. The opening cere-

mony was performed by the Mayor and Mayoress. On Tuesday, at 11.30, the annual sermon was preached in St. Matthew's church by the Very Rev. the Dean of Gloucester (Dean Spence), who took as his text, "Luke, the beloved physician" (Coloss. iv., 14). In the afternoon, after the first General Meeting, a garden party was given at Battledown Court by Col. Rogers, J.P., and Mrs. Rogers. In the evening the President's address was deemed to supply the place of entertainment, and it proved, indeed, most enjoyable.

On Wednesday, after the second general meeting, the Mayor and Mayoress gave a garden party in the lovely grounds of Pittville Park; the element of music on this as on other occasions throughout the Congress being supplied by Herr Wurm's excellent White Viennese Band. In the evening Dr. J. F. Goodhart delivered the address in medicine; and after this the Mayor and Mayoress again acted as host and hostess at an illuminated fête in the Montpellier Gardens. On Thursday the third general meeting was held, and besides the delivery of the address in surgery by Sir William Thomson, C.B., it derived a special interest from the presentation of the Stewart Prize to Dr. Patrick Manson, C.B. Three garden parties then simultaneously followed:—Lieut.-Col. and Mrs. Griffith were At Home at Deanwood; Mr. and Mrs. MacKnight-Crauford at Fullwood Park; and Alderman and Mrs. T. B. Winterbotham at Cranley Lodge.

Thursday evening was devoted to the annual dinner of the association in the beautiful hall of the Boys' College at Cheltenham. Some account of this will be found in another column. After the dinner a ladies' reception was held at the same place. On Friday afternoon an excursion to Gloucester had been arranged, and in the evening a brilliant soirée was held at the Ladies' College, followed by dancing. An excursion to the Wye Valley brought a very delightful week to a close.

#### THE SECTIONS.

The work of the meeting was universally voted, by those qualified to speak, as being fully up to the standard of the best traditions of the Association. Full meetings were the order of the day, although none of the rooms allotted for the purpose were particularly large. The section of obstetrics and gynaecology was, as usual, well patronised, this being one of the branches that appeals most largely to the general practitioner as well as to the specialist. A pleasing feature of this section was the good attendance of lady members, who joined freely in the discussions, and whose remarks were always well received. Nothing of startling interest in the way of new theories or discoveries characterised the proceedings of the sections, but there was good honest work all round. It would be impossible to give here even a summary of the papers and discussions. Many of them were valuable, and will serve as landmarks for future reference. The columns of our contemporary, the *British Medical Journal*, will be well filled with them for some time to come, and to its pages we must refer our readers for the bulk of the matter. We are able to present abstracts of a few of these papers in our columns.

#### THE EXCURSIONS.

On Tuesday, Thursday, and Friday afternoons arrangements were made for trips to Cleve Hill by electric cars. On Tuesday there was an excursion to Tewkesbury, where tea was partaken of at the Bell Inn ("John Halifax's" house); the Vicar of Tewkesbury met the members at tea, and afterwards conducted them over Tewkesbury Abbey. Chedworth and Withington were visited on Thursday, and after a visit to the Roman Villa, Mr. T. L. Robertson entertained the members to tea at Withington Manor. On Friday a trip was made to Birdlip, where the party drove through Cranham Woods, whilst some proceeded to Painswick, where Dr. Balfour Fergusson received them to tea. Among the larger excursions we must first mention the one to Gloucester on Friday. One section went to the Guildhall, where Mr. Bellows gave a short address on "The Place of Gloucester in the Roman History of Great Britain" this was followed by a walk through the city, where Mr. Bellows showed the chief points of interest. Another section proceeded to Barnwood House, where

the Committee of Governors and Dr. and Mrs. Soutar received them at a garden party; a feature of this was the performance of a pastoral play, "Twelfth Night," by Ben Greet's company. A third section went by a later train, and assisted at an "At Home" in the Guildhall, given by Dr. and Miss Batten. During the afternoon the town clerk exhibited some of the city charters and other interesting records belonging to the city; and the very Rev. the Dean of Gloucester accompanied the members over the Cathedral, and gave them a short *résumé* of its history and architecture. On Saturday there was an excursion to the Wye Valley and Symond's Yat. Detraining at Lydbrook Junction, the party walked over the Coldwell Rocks to Symond's Yat, a distance of three miles, the less energetic members doing this part of the journey by train. After lunch boats were chartered at the Yat to convey the members to Monmouth, whence they proceeded to Tintern and inspected the abbey, after tea at the Beaufort Arms Hotel.

Another excursion on the same day was to Cirencester; after partaking of refreshments at the kind invitation of Mr. Oliver Fowler, at Ashcroft House, the party continued in brakes to Earl Bathurst's park, proceeding thence to Sapperton to view the Golden Valley and inspect the church. Tea was served at Cripps' Mead, by kind invitation of Mr. Wilfred Cripps, C.B., and Mrs. Cripps (Countess Bismarck). Two other excursions were also planned, to Great Malvern and Cowley Manor respectively.

#### THE RECONSTRUCTION OF THE ASSOCIATION.

There is no doubt that a large number of members of the Association were drawn to Cheltenham by their interest in the proposed new scheme of reconstruction. It must be gratifying to those who for twelve months have anxiously and laboriously consulted together in the drawing up of the scheme that it was adopted practically in its entirety. The main principles of the scheme were accepted with very little demur, and only very slight alterations in details were either proposed or carried out. Perhaps the most closely contested point was that which referred to the option of members of Council, and some of those who objected most strongly to the principle nearly succeeded in securing its alteration; but the amendment was lost by three votes. There is no doubt that the acceptance of the scheme by the members present at the meetings was in large measure due to the masterly, eloquent, and diplomatic speech of Mr. Edmund Owen, ably supported by Dr. Whitaker and Mr. Victor Horsley. It is gratifying that, considering the importance of the issues at stake, there was remarkably little indulgence in those personalities which have formed a somewhat regrettable feature of some of these meetings; and except for one little incident, in which two former antagonists crossed swords, with perhaps more amusement to the onlookers than serious harm to any one, the whole affair passed off smoothly. It would be premature to forecast the result of these decisions on the future of the Association; but no doubt the principle of delegation must introduce a radical change in the course of time.

#### THE ANNUAL MUSEUM.

Owing, no doubt, in great measure to the energy of the Chairman and Secretary of the Museum and Exhibition Sub-Committee, Dr. H. Bramwell and Mr. G. A. Peake, there was a very good show at the Cheltenham meeting; indeed, we have it on the authority of the President of the Association that this year's annual exhibit was a record one. One factor that made for success was the fact that the exhibition was well housed, and it appeared to be pretty freely patronised. Judging from the numbers of names put down in the exhibitors' notebook, there will be a vast consignment of samples in early course of distribution. Space will not allow anything like a comprehensive survey of the exhibits, and we must be content with mentioning a few of the more novel and interesting objects. Ferris and Co., of Bristol, showed a handsome, compact, and well-filled dispensing cabinet; some convenient vaccination pads and leaves; their universal elastic bandages; and especially their newly-introduced plugging gauze, with the introducer

for the same. The last is a neat and ingenious instrument. The Bath Corporation had a well-made model of the Roman Therms at Bath. Cheltine Foods, Limited, showed their diabetic, dyspeptic, anæmic, invalid and infants' foods, put up in tins and made up in bread and biscuits. Our old friend, Scott's Emulsion, was in evidence, and evidently its popularity is not on the wane. Among Burgoyne, Burbidge and Co.'s specialities we noted a new anæsthetic, acoin, reported to be superior to cocaine in being non-toxic and in giving longer anæsthesia. Frank Rogers showed sprays and atomisers. E. Merck had an imposing array of pharmaceutical products with names of many syllables; among the newest we may note bromopin (an organic substitute for bromides), digitoxin, dionin (a mild, pleasant substitute for morphia), iodopin, jequiritol, and largin (an anti-gonorrhœic). Keen, Robinson, and Co. showed their standard preparations. Among the Vichy waters was a new variety, "Celestins," recommended for kidney disorders. Bovril, Limited, showed their foods, including their special emergency foods for military and other expeditions. Marvis, a dry preparation of fresh fish, was an instance of the growing development of the plan of producing permanent and compact forms of food-stuffs. The Liebig Extract of Meat Co. showed a new meat beverage, Oxo. The Apollinaris Co. had their well-known aerated waters on view. Mellin's Food, Limited, showed among other things a new Mellin's food chocolate. Among concentrate proteid products we noted Casumen and Plasmon; the latter has been mixed in a very palatable form with cocoa. John Weiss and Son had a large selection of instruments, and Down Brothers showed, in addition to instruments, a selection of the newest designs in operating tables. The preparations of red bone marrow, known as Virol, were on view. Stephen Smith and Co. showed their Hall's Wine, Keystone Beef Wine, and Keystone Burgundy; and Brand and Co. showed a number of their well-known products. Somatose was another of the concentrated food-products on view. Parke, Davis, and Co. had several new preparations, such as Adrenalin, an alkaloid derived from the suprarenal bodies; Chloretone, a hypnotic, antiseptic and local anæsthetic; Mercuriol, an antiseptic consisting of mercury and nuclein in chemical combination; Ferrinol, a similar combination of iron and nuclein; and also a nuclein solution. Another important exhibit of high-class pharmaceutical products was that of Bayer and Co. Cadbury Bros. had a cocoa exhibit, where weary sight-seers might be observed recuperating. The enterprising Sanitas Co. showed a number of their preparations, including some of the latest products of Mr. Kingzett's ingenuity, among which we specially noticed Kingzett's Sulphur Fumigating Candles, Kingzett's Sulphugators, consisting of rolls or bandages coated with sulphur; Okol, a new non-poisonous disinfectant said to surpass carbolic acid in its antiseptic and germicidal properties; Kingzett's Formic Sulphugators, an ingenious arrangement for generating sulphurous acid gas and formic aldehyde; and Formitas, which combines the properties of Sanitas and formic aldehyde. Among the newer preparations of Fairchild Bros. and Foester may be noted Enzymol and Diazyme, besides older preparations like Panopepton and Peptogenic Milk Powder. The Shredded Wheat Co. showed the various uses to which shredded wheat could be applied in making nourishing dishes. Harry W. Cox, Limited, had some of their newest apparatus for X-ray work. The Abbey Effervescent Salt Co. showed their special and now well-known preparation. Cosenza and Co. exhibited solidified soups; and the Manhu Co., Limited, showed diabetic foods. Nestlé's Milk was, of course, already familiar; a new form was, however, on view—namely, Nestlé's Viking Milk, which is an unsweetened form. An ingenious bed-rest arrangement was shown by the Automatic Bed-rest Co., of Leamington. Defries and Sons had a selection of filters; and the Sanitary and Economic Association showed some of Dr. Bond's inventions, such as the Euthermic quilt, the floating filter, and the Gelidum ice-store and refrigerator. Allen and Hanburys showed a new Clover's ether inhaler, a new inhaler for use with kylene, a new three-way stopcock for use with gas and ether, a new apparatus for preparing small

quantities of distilled water, and many things besides; while Oppenheimer, Son and Co., among their various well-known preparations, showed a new aeriser, for use with their neboline compounds, and a "universal vapouriser." The Maltine Co. showed the numerous forms in which maltine can be combined with other remedial agents. But we must perforce come to an end, and those who wish for more detailed information will find much of interest in the ample catalogue of 120 pages published by the Exhibition Committee. There can be no doubt about the interest and information to be derived from a visit to such a collection of the books, appliances, drugs and foods which form such an important item in medical and surgical practice.

#### THE ANNUAL DINNER.

The annual dinner of the Association was held on Thursday evening at the Boys' College, when some 350 members and guests sat down. The President was supported, among others, by the Mayor of Cheltenham, the High Sheriff of Gloucestershire, the ex President, Dr. Elliston, the President-elect, Mr. Walter Whitehead, the President of Council, Mr. Roberts Thomson, Sir William Church, Sir William McCormac, Sir Walter Foster, Sir William Broadbent, Sir William Thomson, Sir John Dorington, M.P., Dr. Farquharson, M.P., J. T. Agg-Gardner, Esq., M.P. for the Borough of Cheltenham, Sir John William Moore, Surgeon-General Hamilton, Dr. Parsons, Prof. G. Dook, of Michigan, W. F. Hicks-Beach, Esq., J.P., Professor Fischer, Dr. Darier, Col. Croker-King, Dr. Dawson Williams, Dr. Cholmeley, Lieut.-Col. Griffith, the Town Clerk, Andrew Clark, Esq., Dr. Saundby, Dr. Goodhart, Dr. Ward Cousins, F. F. Leaver, Esq., Howard Marsh, Esq., F. Brandt, Esq., J.P., H. T. Carington, Esq., J.P., Col. Rogers, V.D., C. T. Turnbull, Esq., and Malcolm Morris, Esq. A word of praise must be given to the very artistic menu, which was abundantly adorned with appropriate classical quotations. The usual toast: were duly honoured, but delightful as is post-prandial oratory the organisers should bear in mind that it is possible to have too much of it.

#### THE MEDICO-PSYCHOLOGICAL ASSOCIATION AND IRISH "AUXILIARY ASYLUMS."

It will be remembered by our readers that an attempt is at present being made to compel the Irish Government to sanction the appointment of a layman as head of the proposed Auxiliary Asylum for "chronic harmless lunatics" at Youghal. The importance of preventing such a backward step from being taken will be apparent to everyone who considers the class with which it is intended to people these asylums. We have been given to understand that not alone is a layman to be the head but that the administration of the asylum is to be handed over to a religious order. The Cork Medical and Surgical Association, at a meeting held a couple of weeks ago, passed the following resolution:—"That we, the members of the Cork Medical and Surgical Association learn with extreme regret that it is contemplated to appoint a layman as superintendent to the Youghal Auxiliary Asylum, and that in the interests of humanity we consider a medical man should be appointed, as many of the patients suffer from diseases which at any moment may require prompt and skilled medical treatment to ward off impending death."

At the recent meeting of the Medico-Psychological Association held in Cork, Mr. Graham, medical officer of a Belfast Asylum, read a paper on "Recent Legislation in regard to the Treatment of the Insane in Workhouses." As a result of the discussion which followed, an instruction was sent to the Council to take into consideration the treatment of the insane, as contemplated by the new Local Government Act of Ireland.

On the second day of the meeting the treasurer of the Association, Dr. H. Hayes, said that the Council had taken the matter into consideration that morning, and it had come to the unanimous conclusion to submit to the Association this resolution, in the hope that it would be unanimously adopted:—"It is resolved by the Medico-Psychological Association of Great Britain and Ireland that, having considered the provisions of the Local

Government (Ireland) Act for dealing with the insane, now in workhouses, it views with apprehension any scheme which will permit or favour the aggregation of insane patients requiring institutional treatment, except under skilled resident medical supervision. It is of opinion that all patients in auxiliary asylums should be on the same footing in regard to the Government capitation grant as those in the district asylums." It was considered by the Council that this matter should not, under any circumstances whatever, be considered as a local affair, but as one which affected the Association in all its branches in the United Kingdom, because it was one of the first duties of the Association that it should do its best for the treatment of the insane. It had done its best to forward the most liberal treatment by those who were treated outside under lay care. In all parts of the United Kingdom the single care of patients in homes had been forwarded, especially in Scotland, where there was a large amount of home treatment. There was no reason why the same spirit of liberality should not be accorded to patients in England or Ireland. But it was a quite different matter when it came to the aggregation of cases outside asylums under lay care, as it resulted in neglect, ill-treatment, and other disadvantages, of these patients, who required care and treatment in large institutions with proper medical supervision. They did not for a moment wish that the ideas of mercy and good treatment were in the medical world alone, for they knew that many lay people had the best instincts, and even the most moving resolutions in the matter of the treatment of insanity had come from lay people; but they said that medical supervision was absolutely necessary in caring for large bodies of the insane. Dr. Bolton's paper had shown that there were cases that could easily pass skilled medical attention, and how many more of these cases would escape detection under non-medical supervision. It was the experience of the association that the aggregation of large numbers of patients without proper medical supervision, was a wrong which it was their duty to combat as strenuously as they possibly could. (Hear, hear).

Dr. T. S. Clouston, in seconding the resolution, said he was sure that the gentlemen who brought the matter forward had rendered a service to the insane and to science. (Hear, hear.) He suggested that copies of this resolution be forwarded to every newspaper in Ireland. (Hear, hear.)

Dr. Harvey, Clonmel Asylum, in supporting the motion, said that his committee had come to the conclusion that it would not be for the benefit of the insane to start an auxiliary asylum, and they were giving him three blocks of buildings instead as an extension. (Hear, hear.)

The resolution was agreed to unanimously.

On the motion of Dr. H. Hayes, Newington, seconded by Dr. Urquhart, it was decided to forward copies of the resolution to the Chief Secretary for Ireland, the Inspectors of Lunacy, and others.

We trust that the efforts of the Cork members of the medical profession and of the Medico-Psychological Association will meet with success, and that the gross error which is contemplated will be rendered impossible.

#### A Visit to Bovril, Limited.

On the invitation of Lord Duncannon (the Chairman) and the directors of Bovril, Limited, the members of the British Congress on Tuberculosis visited the laboratories and factory of Bovril, Limited, on Friday and Saturday last. Special interest was manifested in the army rations, samples of which, as supplied to the Nansen, Jackson-Harmsworth, and Wellman Polar Expeditions, were on view. An interesting feature was an exhibit of samples of goods supplied for the Royal Antarctic Expedition, which starts to-day (Wednesday). The process of the manufacture of Virol, the now well-known substitute for cod-liver oil, was shown and explained, and the delegates expressed themselves very pleased with their visit.

#### Death from Poisoning.

An inquest was held on the 28th ult. on the body of Dr. Joseph Wood, of Liversedge, who had succumbed

to an overdose of bromidia taken for the purpose of procuring sleep. A verdict of accidental poisoning was arrived at. The deceased leaves a wife and child.

Apothecaries' Hall of Ireland.

We are requested to announce that at the annual meeting of the General Council of the Apothecaries' Hall of Ireland, the following were duly balloted for and elected to hold office for the ensuing year ending July 31st, 1902. Governor, George A. Stritch, L.F.P.S.G., L.M.; Deputy-Governor, Arthur Atcock, M.D., M.S., E.U.I.

Directors: Hugh A. Auchinleck, F.R.C.S.I., L.R.C.S. Edin.; John Evans, L.R.C.S.I.; William V. Furlong, L.R.C.S.I., L.R.C.P.E.; J. Adam Johns, M.D., T.C.D.; Thomas D. Finucane, M.D.; Edward Hanrahan, M.B., B.U.I.; Robert Montgomery, M.R.C.S.; Robert J. Montgomery, M.B., T.C.D., F.R.C.S.I.; Richard G. O'Flaherty, L.R.C.S., M.B., T.C.D.; James Raverty, L.R.C.S.E.; Joseph A. Ryan, L.R.C.S.E.; James Shaw, L.R.C.S.I.; Charles R. C. Tichborne, L. and D.P.H., R.C.S.I.

Representative General Medical Council: Charles E. C. Tichborne, L. and D.P.H., R.C.S.I.

Secretary: Robert Montgomery, M.R.C.S.

Report of the Annual Meeting of the Medico-Psychological Association of Great Britain and Ireland.

THE sixtieth annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held in the Queen's College, Cork, under the presidency of Dr. Oscar T. Woods, Resident Superintendent of Eglinton Lunatic Asylum, Cork. There were about sixty members present, representing all parts of the kingdom, and a number of important papers were read on various aspects of lunacy. Committees met at 9 a.m., and two hours later the annual meeting began, with the outgoing President, Dr. Fletcher Beach, in the chair. The officers and council were elected unanimously as follows:—President: Oscar T. Woods, M.D. President-Elect: J. Wiglesworth, M.D. Ex-President: Fletcher Beach, M.B. Treasurer: H. Hayes Newington, F.R.C.P.Ed. Editors of Journal: Henry Rayner, M.D.; A. E. Urquhart, M.D.; Conolly Norman, F.R.C.P.I. Auditors: Ernest W. White, M.B.; James M. Moody, M.R.C.S. Divisional Secretaries: South-Eastern Division, A. N. Boycott, M.D.; South-Western Division, P. W. Macdonald, M.D.; Northern and Midland Division, C. K. Hitchcock, M.D.; Scotland, Lewis C. Bruce, M.B.; Ireland, A. D. O'C. Finegan, L.R.C.P.I. General Secretary: Robert Jones, M.D., B.S., F.R.C.S. Registrar: H. A. Benham, M.D. The President (Dr. Oscar T. Woods) who was cordially received, then delivered his presidential address. Dr. John Carswell (Glasgow) read an interesting paper on "The Working of the Inebriates Act," in which he said that this experimental legislation had been a failure. A discussion followed, in which Dr. H. Hayes Newington, of Sussex; Dr. Clouston, Dr. Fletcher Beach, Dr. Urquhart, Dr. Conolly Norman, and Dr. Eustace took part, in which the opinion was generally expressed that the class coming under the Act were mostly incurable, and further legislation was needed to deal with the reclaimable class. Papers were also read by Dr. Thomas Drapes, Superintendent Ennis-corthy Asylum, on "Insanity and Phthisis;" by Dr. F. W. Everige Green, Hatchcroft House, London, on "Evolution of the Colour Sense;" by Dr. E. D. O'Neill, Superintendent Limerick Asylum, on "The Superannuation Question—its Effect on Asylum Officials, with Suggestions for Further Legislation on the Subject;" by Dr. Graham, "Recent Legislation in Regard to Treatment of Insane in Workhouses." The meeting then adjourned. On the second day of the meeting, during the morning, Professors Dixon and Bergin exhibited some excellent radiographs and gave an interesting demonstration of X-ray stereoscopy. Dr. Joseph Shaw Bolton, of Claybury Hall, Essex, contributed a lantern demonstration on "Gross Lesions of the Cerebrum." The Treasurer then submitted the report of the Council on the treatment of the insane as contemplated by the new Local Government Act of Ireland. His remarks will be found in another column. Dr. A. R. Urquhart, Perth, then read a paper on "Effect Upon Patients of Changes of Asylums," and Dr. R. E. Leeper, Resident Physician, St. Patrick's Hospital, Dublin,

contributed a paper entitled "Three Cases of Melancholia: Presenting Symptoms of Unusual Clinical Interest," and he also showed microscopic specimens and photographs. Dr. Dawson also read a paper in which he gave a number of cases in which the drugs suprarenal extract and thyroid extract had given most satisfactory results. A cordial vote of thanks to the President for his services to the Association, and his hospitality to the members brought the meeting to a close.

#### Dublin Death Rate.

THE deaths in the Dublin registration area for the week ending July 27th gives an annual rate of mortality of 21.5 a 1,000. Pulmonary diseases caused 19 deaths. Deaths from tuberculosis were 32, of which 26 were from pulmonary tuberculosis, 3 from abdominal tuberculosis, 2 from tuberculous meningitis, and 1 from peripneumonia. Fifty of the persons who died during the week were under five years of age (36 were infants under one year, of whom 3 were under one month old). Eight children were registered as having died from convulsions; 7 of these were under one year old. How many of them were insured?

#### Irish Medical Schools' and Graduates' Association.

THE summer general meeting of the above association was held in the Ladies' College, Cheltenham, on Wednesday, July 31st. The attendance of members was unusually large, and the chair was occupied by Dr. Mapother, Vice-President. The Council reported that since the annual general meeting the restrictive rule had been repealed in the case of two provincial hospitals. Sir John William Moore (Dublin) said that the subject of the exclusion of those holding the higher diplomas of the Royal College of Physicians of Ireland from candidature for honorary appointments in English hospitals had for several years engaged the anxious attention of the College. After some remarks on the same subject from Professor Thompson (Belfast), the meeting adjourned.

## Pass Lists.

### Edinburgh University Graduation Ceremonial.

AT the summer graduation ceremonial, held last week, the following degrees were presented:—

Degree of Doctor of Medicine: c Robert Oswald Adamson (M.A.), M.B., C.M., with first-class honours, 1889; a Alexander Cruickshank Ainslie (M.A.), M.B., C.M.; John Charles Atkinson, Chiti, M.B., C.M.; a James Martin Beattie (M.A.), M.B., C.M., with first-class honours; c John Macaulay Bowie, M.B., Ch.B.; c Henry Reynolds Brown (M.A.), M.B., C.M.; c Henry Grey Brown, M.B., C.M.; c Robert Nichol Brebner, M.B., Ch.B.; Robert Cathcart Bruce, M.B., C.M.; a Thomas Hastie Bryce (M.A.), M.B., C.M.; Robert Dick Buchanan, M.B., C.M.; Morton Burnet, M.B., C.M.; c Frederick Harold Carlyon, M.B., C.M.; Bernard Ramsay Craig Christie, M.B., C.M.; c Edgar Ferdinand Cyriax, M.B., Ch.B.; Daniel Rees Davies, M.B., C.M.; Walter Dickson, M.B., C.M.; Daniel Charles Edington, M.B., C.M., with second-class honours; b Richard Cogswell Elsworth, M.B., C.M.; David Smart Evans, M.B., C.M.; Gordon William FitzGerald, M.B., C.M.; b Duncan Forbes, M.B., Ch.B., with second-class honours; Thomas Dewar Forbes, M.B., C.M.; a Evan John Hewat Fraser, M.B., C.M., with first-class honours; c Harry Edward Gibbs, M.B., Ch.B. (in absentia); b Alexander Goodall, M.B., Ch.B.; b Thomas Duncan Greenlees, M.B., C.M.; b George Kerr Grimmer (B.A.), M.B., C.M.; Robert Lyall Guthrie (M.A.), M.B., C.M.; b Arthur Cecil Heath, M.B., Ch.B.; Alexander Hendry, M.B., C.M.; b John Thomas Hewatson, M.B., C.M., with second-class honours; c John Hume, M.B., C.M.; b Louis Godfrey Irvine (M.A., B.Sc.), M.B., C.M.; Charles Harold Johnson, M.B., C.M.; William Kinnear (M.A.), M.B., C.M.; William Broad Kirdaly, M.B., C.M.; c Thomas Knowles, M.B., C.M.; a Louis Francis Behagen Knuthsen, M.B., C.M.; c Robert Laidlaw, M.B.; b Gerald Rowley Leighton, M.B., C.M.; b Sreenagula Mallannah, M.B., C.M.; c Thomas Muirhead Martin, M.B., C.M.; George Home Monroe Home, M.B., C.M.; Athelstane Nobbs, M.B., C.M.; David William Horn Paterson, M.B., C.M. c Charles

Edward Potter, M.B., C.M.; b John Vernon Rees Roberts (B.Sc.), M.B., C.M.; b Thomas Arthur Ross, M.B., C.M.; a Alfred Charles Sandstein, M.B., Ch.B. (with first-class honours); a Sutherland Simpson (B.Sc.), M.B., Ch.B.; c Edgar Somerville, M.B., Ch.B.; c Harry Bird Sproat, M.B., Ch.B.; c William Anderson Steven (M.A.), M.B., C.M. (with first-class honours); Gabriel Hendrik Steyn, M.B., C.M.; c George Crowdon Thomas, M.B., C.M.; c William Fookes Thompson, M.B., C.M.; Arthur Harry Hingston Vizard, M.B., C.M.; a Donald Bremner Waters (M.A.), M.B., Ch.B. (with first-class honours); b Andrew Robertson Wilson (M.A.), M.B., C.M. (with first-class honours); Andrew Hamilton Wood, M.B., Ch.B. (a Awarded Gold Medals for their theses. b Highly commended for their theses. c Commended for their theses.)

Degree of Doctor of Science: Alexander Wilmer Duff, M.A., B.Sc.; John Vernon Rees Roberts, M.D., B.Sc.

Degrees of Bachelor of Medicine and Master in Surgery: Manindra Nath Bose, Shaik Dawood, Alfred Thomas Gavin, Paul Eugene Hedwige Giuseppe, John Hally Meikle (M.A., B.Sc.), Wm. Henry Meyer, James Donaldson Sauer, Walter Henry Swaffield, c Harry Moss Traquair, John Wallace, John Owen Williams. (c Indicates that the candidate has passed the examinations with first-class honours.)

Degrees of Bachelor of Medicine and Bachelor of Surgery: David Macrae Aitken (M.A.), John Finlay Allan, Charles Madill Anderson, Robert Vacy Clifford Ash, a Robert Tullis Baillie, James William Barrack, a Alexander Clarke Begg, Raphael Aaron Bellios, John Henry Montgomerie Bell, Vivian Chastel de Boinville, b Richard James Bradley, Edward Seymour Brett, James Brocket, Edward Emslie Brown, Gofina Maude Brown, William Brown, James Brownlee, Robert Wilson Buchanan (M.A., B.Sc.), Henry Buist, b George Cruikshank Burgess, Edward Percy Calder, Kirkland Chapel, Charles Coley Choyce (B.Sc.) Arthur William Stark Christie, Robert Veitch Clark (M.A., B.Sc.), Harry Lechmere Clift, William James Crow, Barbara Martin Cunningham, John Dalgleish, b George Adam Davidson (M.A.), b William Henry Dickinson, a William Elliot Carnegie Dickson (B.Sc.), Thomas George Boswell Dodds, Henry Dodgson, Charles Douglas, James Laing Duncan, William Arthur Duncan, William Inglis Dunn, John Russell Edward, William Eggeling (M.A.), Owen John Evans, John William Falconer (M.A.), b Arthur Marcus Firth (M.A.), Gavin Addie Forrest, Stephen Garvin, James Charles Gilchrist, Ernest Mure Granville, Robert Ashleigh Glegg, Thomas Graham, Roderick McKensie Grant, Arthur Leopold Guernsey, Arthur Rupert Hallam, Agnes Moore Hamilton, Robert Hamilton, William Hamilton, Niels Carl Rudolph Hansen (B.A.), Robert Alexander John Harper, Percival John Hay, Eleanor Russell Henderson, David Colvin Henty, Charles William Howe, a Andrew Hunter (M.A., B.Sc.), Andrew Edwin Hunter, Alexander Rea Johnston (M.A.), George Adam Jolly, Edgar Vaughan Jones, b Andrew Campbell Keay, James Price Kennedy, Percy Vance Langmore, Abdurrahman Khan Lauddie, William Lee, Creighton Hutchinson Lindsay, Samuel Lyle, James Graham M'Bride, Lawson Tait M'Clintock, Hector Kenneth Macdonald, William MacDougall (M.A.), Patrick Frederick M'Farlan, b George M'Farland, Alistair Forbes Mackay, Francis Dillon Scobie Mackenzie, John M'Kenzie, William M'Lachlan, William Mair (M.A., B.Sc.), George William Peak Maitland, Alexander Mowatt Malcolmson, Edward Charles Cecil Maunsell, b George Robertson Mill, Thomas Mill, William Miller, Joseph Miskelly, Alexander Monat, David Munro (M.A.), George Stewart Murray, a Peter Murray (M.A.), William Murray, Elvin Gladstone Osborne Nixon, David Alexander Ogilvie, John Fraser Orr, John Louis Palmer, William Paterson, Walter Scott Patton, John George Peebles, Sidney George Peill, George Pereira, Howard George Pesel, Laurence William Pole, Edmund Thurlow Posts, b William Hogg Prentice (M.A.), Lloyd Turton Price, Henry St. John Randell, Francis Lindsay Rigby, Hugh Moreton Roberts, b George Cook Irvine Robertson (M.A.), John Keith Alexander Robertson, Michael

William Robertson, William Arthur Robinson (B.A., B.Sc.), Andrew Lindsay Roxburgh, Laurence Rundall, a Caleb Williams Saleeby, b Thomas Brown Shaw, Margaret Merry Smith, Thomas Aubrey Smyth, Kate Southon, Henry Langlands Spark, William Clark Speirs, Basil Alexander Spence, Arthur Julian de Spiganovicz, Charles Stanley Stevenson, Mand Muriel Stevenson, Donald Alexander Stewart (M.A.), Ian Struthers Stewart, John Sullivan, Matthew Arnold Swan, Paul Telles, George Lewis Thompson, Thomas Lauder Thompson, John Burnett Thorburn, William Leigh Trafford, Edward James Tyrrell, Abraham Ransome Wallis, Edwin Wells, a Thomas Samuel Beauchamp Williams, Frederick Ernest Wilson, James Woods, David Young. (a Indicates that the candidate has passed the examination with first-class honours. b Indicates that the candidate has passed the examination with second-class honours.)

Special University Certificate in Diseases of Tropical Climates.—Shaik Dawood, M.B., C.M., Charles William Howe, M.B., Ch.B., William Miller, M.B., Ch.B.

Thesis Gold Medallists.—James Martin Beattie, M.D., Thomas Hastie Bryce, M.D., Evan John Hewat Fraser, M.D., Alfred Charles Sandstein, M.D., Sutherland Simpson, M.D., Donald Bremner Waters, M.D.

The Syme Surgical Fellowship has been awarded to Alfred Charles Sandstein, M.D., Ch.B.

The Goodsire Memorial Fellowship has been awarded to Sutherland Simpson, B.Sc., M.D., Ch.B.

The Gunning Victoria Jubilee Prize in Anatomy has been awarded to Duncan Forbes, M.D., Ch.B.

The Gunning Victoria Jubilee Prize in Forensic Medicine and Public Health has been awarded to Charles James Lewis, D.Sc., M.D., C.M.

The Ellis Prize in Physiology has been awarded to Sutherland Simpson, B.Sc., M.D., Ch.B.

The Milner Fothergill Medal in Therapeutics has been awarded to Ernest Francis Bashford, M.B., Ch.B.

The Ettles Scholarship has been awarded to Caleb Williams Saleeby, M.B., Ch.B.

The Beaney Prize in Anatomy and Surgery has been awarded to Harry Moss Traquair, M.B., C.M.

The Buchanan Scholarship in Gynecology has been awarded to William Hogg Prentice, M.A., M.B., Ch.B.

The James Scott Scholarship in Midwifery has been awarded to Caleb Williams Saleeby, M.B., Ch.B.

The Allan Fellowship in Clinical Medicine and Clinical Surgery has been awarded to Thomas Brown Shaw, M.B., Ch.B.

The Monat Scholarship in Practice of Physic has been awarded to James Brownlee, M.B., Ch.B.

The Stark Scholarship in Clinical Medicine has been awarded to William Elliot Carnegie Dickson, B.Sc., M.B., Ch.B.

The Murchison Memorial Scholarship in Clinical Medicine has been awarded to Robert Veitch Clark, M.A., M.B., Ch.B.

The Pattison Prize in Clinical Surgery has been awarded to John Saffley.

The Gilfillan Memorial Prize has been awarded to Agnes Moore Hamilton, M.B., Ch.B.

The Cameron Prize in Therapeutics has been awarded to Patrick Manson, C.M.G., M.D., for his researches on the transmission of diseases through the mosquito.

Royal College of Surgeons, Edinburgh.

The following gentlemen having passed the requisite examinations were, at a meeting of the College, held on July 30th, elected ordinary Fellows: George Alexander, M.B., Ch.B., William H. G. Aspland, M.B.C.S.Eng., L.R.C.P.Lond., Alexander Girvan, M.B., C.M., Patrick Kinmont, M.B., Ch.B., William T. McArthur, L.R.C.S.E., Angus Macdonald, M.B., C.M., Stuart A. Ord-Mackenzie, M.B.C.S.Eng., L.R.C.P.Lond., Arthur Davies Peill, M.B., C.M., George H. Pooley, L.S.A.Lond., Matthew A. Reid, M.B., C.M., Edward Robertson, L.R.C.S.E., Frederic H. Sturdee, M.B.C.S.Eng., L.R.C.P.Lond., and George F. Vincent, L.R.C.S.E.

## Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at the office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

### JULIUS ROBERT VON MAYER.

The Association of German Engineers have just placed a memorial tablet on the house in Heilbronn in which J. R. von Mayer was born. He studied medicine at Tübingen, Munich, and Paris, and commenced the practice of his profession as a ship's surgeon, and settled as a general practitioner in his native town in 1840. In 1842 he published in Liebig's *Annalen* a preliminary statement of the mechanical theory of heat, in which he clearly demonstrated the numerical relation between heat and work. Seven years before his death he was awarded the Copley medal of the Royal Society, London; in 1876 he was ennobled by the King of Württemberg. He died on March 20th, 1878.

It is peculiarly gratifying to us to see the memory of deserving members of the medical profession duly recognised, and we in no way withhold our own praise; but we cannot help thinking of Dr. Beade, of Cork, whose house bears no memorial tablet, although, in 1808 (34 years previously), he made the discovery, performed the experiment, and announced the law for which, to-day, a German, Mayer, is so honoured.

DR. S. Y. B.—It is doubtful whether pennyroyal, in medicinal doses, has an effect on the pregnant uterus; nor has errot, in spite of the affirmation of medicologists, any abortifacient action, except possibly in the later stages of gestation. The subject is one which urgently calls for further careful study, though the law takes cognisance more of the intent than of the actual effects.

X. R.—Your observation is defective in that the diagnosis does not appear to be placed beyond question. It is obvious that any shortcoming in this respect must invalidate your conclusions, and for this reason we do not think it wise to publish it.

### SHOCKING!

The newspapers state that one of the internes in a Brooklyn hospital is under discipline for having kissed, or rather for having been caught kissing, one of the young and comely members of the training school. We trust such practices will not spread from the new world to the old!

VULNERABLE PARTS OF THE HUMAN ANATOMY.—The murderers have discovered some astonishingly vulnerable parts of the human anatomy of late. From a paper this morning we learn that a Georgia colonel was "shot in the ticket office"; the other day a man was fatally shot "through his door," and not long ago another received a fatal wound "in his window."—*New York Commercial Advertiser*.

MR. JAMES BLAIR.—We are unable to trace the allusion to iodobenzoyl iodide of ammonium in the treatment of broncho-pneumonia. You might apply to Merck, of Darmstadt, or his London agent.

DR. E.—We are not particularly interested in the subject you have chosen for your communication, and the list is at your disposal.

MR. S. M.—Pressure on our space obliges us to hold over your paper for the present. We hope, however, to publish it ere long.

DR. SINGLAIR.—Your letter received too late for insertion in this issue.

## Appointments.

- BELFRAGE, SYDNEY H., M.B., L.R.C.P.Lond., M.R.C.S.Eng., Assistant Anaesthetist to the Dental Hospital of London.  
 BERRYMAN, EDMUND N., L.R.C.P.Lond., M.R.C.S.Eng., District and Workhouse Medical Officer of the Llandoverly Union.  
 BURGESS, ARTHUR H., F.R.C.S.Eng., M.B., Ch.B., M.Sc.Vict., Surgical Officer and Medical Superintendent of the Manchester Cancer Pavilion and Home.  
 HAWORTH, STREANER R., M.D., B.Ch., R.U.I., District Surgeon of Bredesdorp, Cape Colony.  
 HEWLETT, RICHARD TANNER, M.D., M.R.C.P.Lond., Professor of General Pathology and Bacteriology in King's College, London.  
 PABRETT, EDWARD E., L.R.C.P.Lond., M.R.C.S.Eng., Assistant Medical Officer at the Brentford Infirmary, Workhouse, and Schools.

- PARSONS, CHRISTOPHER T., M.D.Lond., Medical Officer for Receiving School for Children at Parson's Green.  
 THOMSON, ST CLAIR, M.D., M.R.C.P.Lond., F.R.C.S.Eng., Assistant Physician for Diseases of the Throat in King's College Hospital.  
 WATSON, JAMES, L.R.C.P., L.R.C.S.Edin., has been appointed District Medical Officer of the Ailwinck Union.

## Vacancies.

- Birmingham and Midland Skin and Urinary Hospital, John Bright Street.—Surgical Assistant for six months, renewable. Honorarium at rate of 50 guineas per annum.  
 Brecon Infirmary.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, and attendance.  
 Brighton, Hove, and Sussex Throat and Ear Hospital, Church Street, Queen's Road, Brighton.—Non-resident House Surgeon. Salary at rate of £75 per annum.  
 Bristol General Infirmary.—Casualty Assistant House Surgeon. Salary £50 per annum, with board, residence, &c.  
 Carlou Union.—Dispensary Midwife. Salary £28 per annum. Applications, enclosing diploma and testimonials, to the Presiding Chairman. (See Advt.)  
 City of London Hospital for Diseases of the Chest, Victoria Park, E.—Second House Physician for six months. Salary at rate of £30 per annum, with board, residence, and washing.  
 Devon County Asylum, Exminster.—Third Assistant Medical Officer. Salary commencing at £125, and increasing at the rate of £10 per annum to £155, with board, residence, &c.  
 Devonshire Hospital, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.  
 Guest Hospital, Dudley.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.  
 Kent and Canterbury Hospital.—Assistant House Surgeon, unmarried. Salary £60 per annum with board and lodging.  
 Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary £100 per annum, furnished apartments, &c.  
 Liverpool Dispensaries.—Assistant Surgeon. Salary £100 per annum with board and apartments.  
 Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, increasing £10 every year, with furnished apartments, attendance, light, and fuel.  
 Oxford, Combined Rural and Urban District Councils of.—Medical officer of health. Salary £750 per annum.  
 Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board (excluding stimulants) and apartments.  
 Royal South Hants and Southampton Hospital.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with rooms, board, and washing.  
 Rubery Hill Asylum, Barnet Green, Worcestershire.—Junior Assistant Medical Officer. Salary £130 per annum, with board, furnished apartments, &c.  
 Somerset and Bath Lunatic Asylum, Wells, Somerset.—Medical Superintendent. Salary £600 per annum, with furnished house and allowances.  
 University of Glasgow.—Examiner for Degrees in Medicine and Science. Salary £30 per annum. Applications, enclosing testimonials, to Alan E. Clapperton, Secretary. (See Advt.)  
 Urlingford Union.—Trained Night Nurse. Salary £50 per annum. Application, enclosing diploma and copies of testimonials to M. P. Dowling, Clerk of Union. (See Advt.)  
 Victoria Hospital, Folkestone.—House Surgeon. Salary £100 per annum, with board, residence and laundry.  
 West Africa.—Three Medical Officers. Salaries offered £40 per month, plus subsistence allowance, first-class passages, and outfit allowance.  
 West Herts Infirmary, Hemel Hempstead.—House Surgeon, single. Salary £100 per annum, with furnished rooms, board, fire, lights, washing, and attendance.

## Births.

- CALEY.—On July 29th, at Colville House, Ealing, the wife of Guthrie Neville Caley, M.D., of a son.  
 LANGFORD.—On July 25th, at Weston Park, Crouch End, N., the wife of C. Harris Langford, M.B.Lond., of a daughter.

## Marriages.

- EVANS—BEENHAM.—On July 23rd, at St. John the Divine's, Richmond, David Robert Powell Evans, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A., to Jessie, daughter of Charles Beenham.  
 HORSFALL—CAMPBELL.—On July 24th, at Ho'y Trinity, Melrose, Charles Edward Horsfall, M.B., Bedale, Yorkshire, to Lillias Marianne, daughter of Robert Hume Campbell, of Glendaruel, Argyshire.  
 STABB—FROUDE.—On July 30th, at Marylebone Parish Church, Ewen Carthew Stabb, F.R.C.S., of 57, Queen Anne Street, W., eldest son of William Henry Stabb, of Ilfracombe, to Emma Langworthy, daughter of the late James Henry Froude, of Newent, Glos.  
 WATTS—TASSELL.—On July 31st, at St. Andrew's Church, Fulham, Alexander Minter Watts, M.B., B.S., of Tollthorpe House, Holbeach, Lincolnshire, son of Captain James Samuel Watts, R.N., to Grace Evelyn, fourth daughter of the late Robert Tassell, Esq., of Bocky Hill, Maidstone, Kent.

## Deaths.

- HORSFALL.—On July 23rd, at Newland House, Leamington Francis Horsfall, M.R.C.S.Eng., L.R.C.P.Edin., aged 80 years

## Original Communications.

### RESIDUAL LUNATICS AND RECENT LEGISLATION.

By M. J. NOLAN, L.B.C.P. & S.I.,

Resident Medical Superintendent, Down District Asylum.

By the term "residual lunatics" I propose to designate collectively the groups of insane persons at present located in the wards of the workhouses throughout Ireland. The "recent legislation" to which the title refers embraces those clauses (Sec. 76 (1), (2), (3), and (4) of the Local Government (Ireland) Bill, 1898, which have been enacted to ameliorate the miserable condition of the comparatively small proportion of the insane members of the community comprised in the above-mentioned groups. The object of this communication is to consider the consequences which may follow the operation of the Act, if the clauses are put into practical effect, without some necessary precautions.

The adoption of the term "residual" in preference to the words of the 76th sec. "not dangerous to themselves or others," needs no apology to recommend it to those who understand that no one expression can adequately convey an inclusive idea of the various psychical conditions which are the characteristics of the thousands of mentally affected persons still retained in the workhouse. Elsewhere to the public I have pointed out that the expression "chronic harmless lunatic" is a crude legal term, convenient perhaps, but faulty certainly; that the "harmless" and "dangerous" phases in the popular acceptance of those terms are often interchangeable; and that we who spend so much of our lives in the association with the insane would hesitate to ascribe a limit to the potential "dangerous" element in an apparently "harmless" lunatic. It must then be admitted at the outset that the looseness of a popular term to indicate the chief features of some thousands of persons who have little in common apart from poverty, location, and mental degeneration in all its varying aspects, must needs lead to contingent errors in its application. "Dangerous," *vide* the dictionary, means "perilous, hazardous, exposing to loss, unsafe, full of risk," and as exemplification the great Macaulay quotes, "*It is dangerous to assert a negative*"; not inapt in the present instance, when the parliamentary draughtsman has converted so many entities into one huge cypher—pathological entities, no doubt, but they count for something when they come into our calculations for asylum accommodation. To those who have lived among the insane nothing, perhaps, is more striking than the working out every now and again of the "unknown quantity," so to speak, in the problem of a disordered mind. That "it is

the unexpected that always happens" is equally true of sane and insane. One morning we are astonished when Vere de Vere, an exclusive aristocrat, marries his cook; suddenly, too, an apparently passive weak-minded patient develops an acute paroxysm of suicidal fury, and reveals an unsuspected volcano of passionate feeling. In an ordinary asylum the "chronic harmless lunatic" (whose name judging from the free use of the term would indeed be Legion) is in point of fact a by no means common individual—passive, weak-minded creatures no doubt abound, but certainly they are not free from risk of physical and moral injury to themselves and others. That this apparently "harmless" state of quiescence is largely due to the asylum environment which supplies the asylum backbone to these psychically invertebrate people, is sadly illustrated by the following case:—J. S., a good-looking, intelligent, middle-aged man, of kindly habits, gentle disposition, and little strength of character had lived in the asylum for years. He was admitted suffering from mild melancholia due to business losses, but being of an easy disposition soon reached his normal level, which had been marked by a tendency to lean on others for moral support. During his illness his wife and family emigrated, so his immediate ties were severed. He professed his inability to face the world afresh in view of the altered circumstances, but worked well and willingly in the asylum. He became a "liberty patient," working alone in the garden, going to the country for walks, and acting as a messenger. He was clean and neat in his habits, careful in his dress, solicitous about his health and personal comforts, and always declared he hoped some day to begin life again outside the asylum. After years the crave for liberty predominated over his other feelings. Every effort to get him work and a home was unsuccessful. He at last besought that he should be sent to the workhouse of his district, where he was confident he could act as a wardsman, and would not be regarded as a "lunatic." His wish was granted; he left the asylum full of gratitude and hope, buoyed up by the good wishes of all, as he had been a favourite; and with a sense of independence as he was the recipient of a small outfit and a little money—parting gifts from the staff. Some few weeks later the master of the workhouse reported that he had escaped; the guardians directed that the wall of the lunatic airing yard should be raised several feet to prevent a recurrence of such conduct. Meanwhile search was made for the missing man, but no trace could be found. Weeks passed by, when one of a number of inmates sent by the master to do some work in a detached building wandered to the upper room of the house, where, to his horror, he found a shockingly decomposed corpse of a man, suspended from the rafters, and gnawed by rats. This was the sad end of one who was, apparently, a typically "harmless" unatic; had he been detained in the asylum he

would, no doubt, have lived out his natural life a useful member of the community in which his lot was cast. There are in asylums, at present, scores of similar apparently "harmless" lunatics, who require the moral support of their environment to protect them from some such fate. Medical superintendents of districts asylums are well aware that the cases which heretofore have been transferred from the workhouses are, by no means, as a rule "chronic harmless lunatics." Chronic, indeed, they too often are; but very frequently full of risk to themselves and others, as well as advanced in disease or age, or both. When chronic their habits are usually dirty, destructive and erotic, and when physically ill they exhibit the cachexia of air starvation incidental to their close confinement. Taking them all round they are, perhaps, on the whole the most troublesome, expensive, and most unsatisfactory, from a medical standpoint, of the year's admissions. They require all the control, care, and comforts that our asylums can afford. Is there any reason to believe that those still remaining in the workhouse wards will not exhibit, wherever located in the future, the same urgent conditions sooner or later? Does anyone with the most elementary knowledge of the circumstances suppose for one instant that if the residual lunatics of any county were brought *en masse* tomorrow to the county asylum of the district, the motley consignment of degraded humanity could be fittingly housed in a "chronic block." Would it not be the first and obvious duty of the superintendent to distribute them according to their physical and mental state, over the appropriate departments of his institution? Yet it is such a group it is proposed to place in an "auxiliary" and to maintain at a cost of some 5s. 6d. per week, of which the local taxation account is to contribute 2s. per head. So far then, it would seem that the provision necessary for the requirements of the residual lunatics is based on a misconception of their characteristics, and has, moreover, been very much underestimated seeing that they in no respect differ from those of the same class heretofore sent to asylums, where they cost the maximum sum for maintenance and tax the full resources of those institutions. It is also evident, as sadly illustrated by the case of J. S. that the comparatively small number of mild chronic cases of an apparently "harmless" character cannot be removed without risk from the district asylum where, moreover, they are for the most part willing helpers in the daily work, and so reduce the cost of paid labour. These chronic lunatics require the asylum environment, and the asylums as at present constituted require the assistance of this class to help in every department of labour, and so lighten the general cost. It is clear then, as has been abundantly proved by the complete failure of the clauses of the Lunatic Asylums (Ireland) Act, 1875, that transfer from asylums to workhouse wards should be avoided for every reason. It may be argued without fear of contradiction that the same reasons will still hold good wherever it is proposed to transfer apparently "harmless" chronic lunatics from the District Asylum to any institution of the proposed "auxiliary" type—in other words, to a few isolated wards grouped under the condition of workhouse life and forming receptacles for incurables, many of whom have yet wit enough to read and sensibility enough to be injuriously affected by the inscription writ so largely over its door—"Abandon hope all ye who enter here." So much, then, for the difficulties which attend the selection of cases for the "auxiliaries." Let us now see how the auxiliaries themselves are to be provided.

In February of this year the Local Government Board issued a circular to the County Councils, in which it was pointed out to these bodies that:—

"The following courses are now open to a County

Council, who should consider how any action of theirs might affect both asylums and workhouses:—

"1. To build a separate auxiliary asylum for chronic harmless lunatics, with a resident medical superintendent, and at least one assistant medical officer (Local Government Act, Section 84).

"2. To add, subject to the Lord Lieutenant's direction, by the erection of buildings less elaborate than the original ones, a new department to an existing asylum, and to place it under the resident medical superintendent of that asylum.

"3. To acquire and adapt some workhouse or other building, either as a separate auxiliary asylum, or, if the Lord Lieutenant so direct, as a department of some existing asylum."

Since this circular was issued some six months ago public attention has been directed to the subject in the general and medical press, and it may be taken as fairly representing the state of opinion to-day, with regard to the different courses, that No. 1 is impracticable because of its small numbers to be provided for, say 4,000 spread over twenty-two districts, or 180 to each. Beyond a reduced capitation grant the constitution of the auxiliary from an administrative point of view would in no way differ from the existing district asylum.

No. 2 has been considered feasible to some extent, but it creates a crop of difficulties by introducing a second class treatment, so to speak, side by side with what has been already approved—two systems under the same management and one roof.

No. 3 has found little favour, inasmuch as the circular of the Local Government Board suggests that it would be cheaper to build new than to adapt old buildings. This statement has been supported by the estimates received for converting workhouses into auxiliary asylums. Financially the adapted workhouse as an independent asylum is open to the same objection as No. 1, and as a "Department" "of an existing asylum" to the same objection as No. 2.

An examination of the propositions set forth in the circular when based on a full knowledge of the conditions which practically affect the questions regarding the due care, proper supervision, and adequate treatment of the insane brings to light the following facts:—

1. That in the words of the Local Government Board's circular, "humanity demands" the removal of the 4 000 insane from workhouses, who must be provided for elsewhere.

2. That the class of patient for whom auxiliaries are proposed cannot be conveniently, beneficially, or economically grouped in such institutions.

3. That the accommodation proposed would under Schemes 1 and 2 be as costly, and the administration more expensive than that of existing asylums, though nominally established on economical lines for the less curable cases.

4. That no asylum can be properly carried on at a minimum cost of 5s. 6d. per head, and that the cost in an "auxiliary," either as a separate institution or a department, would exceed that figure, hence the 2s. grant is inadequate.

5. That in face of all the circumstances, the number and nature of the persons to be dealt with, the object in view, the financial aspect of the question—the only one, I regret to say, the public has seriously considered,—the creation of "auxiliaries" is unjustifiable, and that the wisest course, in the ordinary country districts at least, is to increase the existing asylum accommodation on the ordinary lines. In large urban districts, or conjoint districts, other steps may perhaps be taken with advantage, such as boarding out, or by erecting additional asylums.

Whether or not lunacy is on the increase is a more or less problematical question we need not

stop to consider, since the stern fact remains that the need of asylum accommodation is yearly increasing, and that the Act of 1898, with one stroke, has practically certified some 4,000 individuals of unsound mind, now located in workhouses. These persons are collectively, and for the first time legally, declared to be insane. It is recognised that they are in urgent need of adequate care; and it is provided that they may be (under the special conditions enumerated in the different courses set forth in the explanatory circular of the Local Government Board) removed elsewhere. This recognition of the malady has been long desired; if tardy, it is none the less welcome, but what can be said of the proposed remedy, but that it is of a weakly palliative kind, altogether inadequate to touch the root of the matter, and of that class of cures which are proverbially worse than the disorder they are applied to ameliorate. The establishment of starved "auxiliaries" on the lines indicated is not the course to bring these unfortunates to their destination; it is simply sending them to lie on a siding until the block is cleared in the main line to their proper terminus. In this siding they may remain for an indefinite period, suffering the miseries of isolation and its consequences, while their late companions on the journey are going gaily along. *En passant* note may be taken of the time this new departure takes place, as it is verily a psychological moment in the history of Irish Bumbledom. For to-day we find boards of guardians discussing menus of improved dietaries, trained nurses are displacing "Gamps" and "handy women," sanitation is at last asserting its importance in all departments of public health; the same epileptics are to find a haven in central homes; the children are to be removed to the more beneficial surroundings of district schools; the unfortunate consumptives are at last to have pure air and an abundance of it in sanatoriums. The new broom finds plenty of work in clearing out the dirty corners. When the reformed house is swept and garnished the "Societies for Brightening Workhouse Life" come along with music and song to cheer up the dreary days of the penal imprisonment of abject poverty. So the removal of the chronic and euphemistically dubbed "harmless" lunatic is necessary—the most repulsive and glaringly reproachable object must forthwith be swept into the outer darkness. One is inclined to ask, how does it come about that now when at last the dawn appears rosier for the pauper than he who is the veriest pauper of all—one bereft of means, of health, and of mind—is condemned to an existence which experience has shown could not be adequately supported in the past on the same provisions which it is proposed to dole out to them in the future? In point of fact, he is not only to stand still, but to go down hill, when all his former companions cry "Excelsior." Herein lies the practical point of this new departure. *The estimated cost of a lunatic in an auxiliary is fixed at a sum which has in the past proved absolutely insufficient to supply in the most meagre manner the limited wants of the afflicted poor of all classes in our workhouses.* It must be conceded also that the amount of relief granted to reduce local taxation is hopelessly inadequate to appreciably lighten the burden which proposed "auxiliaries" would, if established, throw on the taxpayer, that is to say, if these auxiliaries are to be created for the betterment of the chronic insane. But why create yet another class of institution in this small country already weighed down with too many institutions of all kinds? Such a course objectionable from medical and financial standpoints, can be avoided by increasing the accommodation of the county asylums, when the lunatics sent to them would benefit by appropriate surround-

ings, and the counties benefit by the larger grant. To this it may be urged that the county asylums are in some few districts too large to admit with advantage of a greater growth; possibly too some few superintendents who find themselves daily beset by the worries of the cramped conditions of crowded wards may say that instead of an increase they desire a reduction in the number of the patients. Such objections can be easily swept aside. If a district asylum has reached the stage of unwieldy bulk by all means let it be reduced by the creation of a legitimate branch of the same constitution, and not propagated by a "sport" of degeneracy such as an "auxiliary" would prove to be. The superintendent who seeks to throw off the embarrassment of accumulated cases should consider the broad question of the treatment of the chronic insane with a view to the general conditions, and not to local exigencies. It is particularly dangerous for those superintendents whose asylums in the sister countries have been raised to the highest possible point of excellence in general equipment, in the development of special departments for scientific research and in the cultivation of classical clinics, to take a summary view of the disposal of the chronics. No doubt in the fulness and amplitude of their administrative powers and success they feel that, while the "chronic" still crowd their wards, the idol of perfection they have set up has still but feet of clay. To such superintendents it may be said: If you, having done all any one individual can humanly do for the 1,000, 2,000, or 3,000 patients under your care, find that the "chronics" do not appreciate the æsthetic comforts of your corridors, that your laboratory shelves groan with the unexplored pathological material of a kind which offers no prospect of new or attractive work, that "the babbling of green fields" of the dement does not fix with the same interest the attention which your clinical class gives to the highly-seasoned fabrications of a delusional adolescent; if for these reasons you deem it desirable to be rid of the incubus, pray be mindful that the one has as full a claim on the public purse as the other, and that it is outside your province to suggest the restriction of the legitimate comfort of demented old age in order to indulge the more recent cases in what you admit is the border land of luxury. Remember also that you are rolling along in urban areas on the hub of civilisation, and be not unmindful of others less fortunate than you who have to labour along the rut in country districts. Having successfully passed the goal, do not forget that others have but started in the race of progress. Let not your specialty sink the broader spirit of humanity that alone can alleviate the actual living suffering which the highest microscopic power has, as yet, failed to locate, though its effects are palpable to the most unobservant." But it needs no reasoning to prove to the medical reader how "auxiliary" asylums of the projected type are unsuited to the wants of the class they are intended to accommodate, any more than it requires other proof, than is established by an examination of the financial aspect of the question, to show that such institutions are unacceptable to over-taxed ratepayers. Still, the necessity for some accommodation remains, and the problem is how is it to be met? A section of the laity indeed have, in the profound ignorance of the real conditions, sought to cut the Gordian knot by proposing "auxiliaries" so-called, to consist of adapted buildings, supervised by a person of the status of a head attendant and supported by "a few vigorous women, neither squeamish or over-refined." It is unnecessary to dwell on this project save to record it as, perhaps, the most astonishing proposition of an age, characterised by astounding projects, from all of which, however, it differs in the

fact that it is as retrograde as others are progressive in character. In its simplicity lies its danger.

It seems akin to the line of reasoning which a few years since made it seem clear to a certain section of Parisian "souls," that the best means to promote the highest spiritual feeling and to divest themselves of the trammels of our too elaborate system of modern life, rendered it necessary that they should migrate to the woods of Normandy, where, substituting fig-leaves for chiffons, they should resume the unfettered simplicity of promiscuous association! Amidst sylvan delights they were to dig up roots for food, and enjoy sexual relations of so primitive a kind that rendered formalities unnecessary—but these are details. One can readily conceive, however, that the details of life in an "auxiliary" run by those sturdy, coarse women, would furnish scenes no less novel and sensational which would horrify no one more than the ecclesiastical dignitary who, in the fulness of his heart, but with a want of the due knowledge of collateral circumstances, outlined a benevolent scheme for the benefit of his flock.

Few legislative Acts there are that do not require amendment, and no Act, perhaps, dealing with the insane ever so urgently demanded amendment as the Local Government Act, 1898, where it touches the provision for the chronic insane. And yet a very little change may set the matter right, as it only needs some precautionary clauses and a little more liberal pecuniary treatment to make the evident intention of the Legislature practical and efficient. Let the auxiliary buildings be still provided, proximate to the district asylums, let the 4s grant be given to each patient therein, and let the transfer of patients from the parent asylum, and the auxiliary be rendered as easy as the changes in the mental and physical states of the patients are rapid. This is not too much to ask in face of a decreasing sane population, an increasing insane community, and a local taxation account based on a standard year, when every department of the Poor-law service was notoriously inefficient owing to financial starvation. Excellent in intention, but hopelessly weak in effect, the Act offers a temptation which carries with it certain punishment. The 2s. grant will fall far short of the wants of the chronic lunatic if *adequately* provided for in an "auxiliary," and the deficiency must be drawn from local resources already suffering from overstrain. Let every certified lunatic get the benefit of the 4s. grant, and treatment of a rational kind in suitable asylum wards, and then the evil ceases to exist. The cure is palpable, and should be recommended to those who can exercise it for the dual benefit of the afflicted insane and the hard-pressed taxpayer. The grant of the larger sum would be of infinitesimal consideration in the Imperial Budget, yet it would be for a section of the community "an indemnity for the past, and a security for the future."

### CERTAIN POINTS IN THE OPERATIVE TREATMENT OF RENAL CALCULUS. (a)

By J. HUTCHINSON, jun., F.R.C.S.,  
Surgeon to the London Hospital.

IMPROVED methods in skiagraphy have rendered it possible to detect renal calculi whatever their composition, so long as the subject is not exceptionally stout or the calculi exceptionally small. The time required for a successful exposure to the X-rays can be brought down to fifteen or even ten seconds, which may be regarded as instantaneous photography.

(a) Abstract of Paper read at British Medical Association Annual Meeting, 1901.

During this short exposure it is easy to avoid all blurring from respiratory or other movement on the part of the patient. Uric acid calculi give better results with these short exposures than with the long ones that have been hitherto customary. The exact size, number, and position of stones in the kidney can thus be determined before the operation, and the kidney subjected to the smallest degree of injury during the latter. In the majority of cases renal calculi can best be reached through an incision across the back of the pelvis, though it is necessary in some cases to go through the cortex. With the aid of the X-rays it will be almost always possible to place the incisions directly over the stone or stones. To bring the kidney out into the wound is sometimes both difficult and dangerous, and to bisect it through the convexity (splitting the organ) may cause serious hæmorrhage, or lead to a urinary fistula. Provided the urine is fairly aseptic, a condition which can be generally brought about by the previous use of urotropine, a wound made through the pelvis, whether sutured or not, will heal readily. If sutures are used they should be of the finest silk, and should not penetrate the whole thickness. The X-rays enable very small calculi to be detected, and they should be removed by operation as soon as this is done, since small solitary calculi are among the most dangerous of all.

Occasionally whilst the calculus is on one side the patient's symptoms are referred to the other. A striking instance of this was narrated, in which the X-rays prevented a serious mistake being made. The evidence of skiagraphy confirms the belief that stones occur simultaneously in both kidneys in the proportion of about one to fifteen one-sided cases. This information may be of the utmost importance to the surgeon before operating.

By means of the X-rays in some cases a supposed renal tumour or hydronephrosis may be shown to depend on a small impacted calculus, and thus nephrectomy be avoided. Since such reliance can be placed on the evidence of the X-rays in skilled hands, it is obvious that the operation of nephrolithotomy in the absence of a stone will become much less frequent than has been the case.

Exploratory nephrotomy is not without risk and (supposing there is no calculus found) very little may be gained by the operation. It is, however, admitted that a few cases of nephralgia are permanently relieved by it.

The paper contained cases illustrating the above points, and technical details as to the best methods of skiagraphy in renal calculus.

### THE ROLE OF TOXIC ACTION IN THE PATHOGENESIS OF INSANITY. (a)

By Dr. FORD ROBERTSON.

HIS own views, he observed, were based chiefly upon the recorded observations. Whatever else mind might be, it was, in the first place, a product of the functional action of certain of the cerebral neurons. For the normal manifestation of this functional action three factors are essential, namely, (1) Integrity of the anatomical elements which form the physical basis of mind, (2) the maintenance of suitable nutritional conditions of these neurons, and (3) those sensory impulses which, commencing to impress the anatomical elements at an early period of life, gradually endow them with their special functional power and of which the almost continual stimulus is required in order to call these func-

(a) Introductory remarks to a discussion at meeting of British Medical Association, 1901.

tional powers into action. Morbid mental action might primarily depend upon a fault on the part of any one of those factors. He discussed the importance that was to be attached to a fault in the cortical neurons in the pathogenesis of insanity, and the parts played by sensory impulses and by alterations in the nutritional conditions. There were two respects in which the materials brought to the neurons by the blood vessels might be unsuitable for their healthy nutrition. There might be a deficiency of certain constituents which were needed for their normal metabolism, or certain substances might be present which were taken up by the cells and then disordered their metabolism. Any such substance was a toxin. He enumerated the various possible non-toxic primary etiological factors in the pathogenesis of insanity, and contended that, when these were fully taken into account, there remained a very large majority of cases of insanity in which the primary etiological factor was toxic action. He entered shortly into the question of the nature of predisposition to insanity, and pointed out that it was based upon at least three entirely different conditions. By far the larger proportion of such predisposition depended not upon any condition that could rightly be termed degenerative, but merely upon one extreme of those wide though limited differences that individuals exhibit in the reactive qualities of their cortical neurons to various forms of toxic action. He insisted strongly upon the importance in certain cases of the indirect action of toxins upon nerve-cells through injury to the nutrient vessels. The various toxic conditions which tended to affect the nerve-cells might result from (1) exogenous toxic agents, (2) infections, and (3) auto-intoxication and auto-infection. In these respective categories special importance was attributed to alcohol, syphilis, and auto-intoxication and auto-infection from the gastro-intestinal tract. He dealt especially with the last named, and maintained that it had far greater importance than was generally believed. In his opinion various forms of toxæmia of gastro-intestinal origin were the chief factors in the pathogenesis of a large array of acute and chronic diseases, including several forms of mental disease. He mentioned especially arterio-sclerosis, senile insanity, general paralysis, locomotor ataxia, chronic alcoholic insanity, dementia præcox, acute and chronic mania and melancholia, idiopathic epilepsy (as the determining cause of the fit), and chronic Bright's disease. He held that the large majority of cases of insanity were not primarily diseases of the brain at all, but depended upon the action of toxins derived from elsewhere, which affected the functional activity of the cortical neurons by disordering their metabolism and often permanently damaging and even destroying many of them. He agreed with Dr. Mercier that "insanity is a disease of the whole man, a disease of the whole organism, which can only be properly understood and properly dealt with when so regarded."

### SOME POINTS IN THE MANAGEMENT OF ECZEMA. (a)

By HENRY WALDO, M.D., M.R.C.P.,

Physician to the Bristol Royal Infirmary, and in charge of the Department for Diseases of the Skin.

THE author urged that an attempt should always be made to cure eczema. Whether it depended upon the action of micro-organisms, or whether this is disproved, as Kaposi thinks, by the fact that eczema may be provoked at will in any part of the skin of any person by mechanical, chemical, or thermal

stimuli, he considers that daily cleansing the part affected with the juice of bran, or starch, or boiled oatmeal diluted with rain-water, should be carried out.

He thinks the sound parts of the skin should be washed daily with soap and water, as by so doing the eczematous surface is much benefited, and illustrated this by stating that if a different application is used for each side of the body in a symmetrical eruption, it must not be taken as a test of the relative value of the two agents, as one side always responds to a successful treatment of the other. This sympathetic relation of the two sides should be therefore taken into account by cleaning and polishing the general surface of the body which is not the seat of disease. He advised soothing or stimulating applications to protect the part, and to a wet eczema he thinks a lotion is better able to come into close contact with the living tissues. He believes internal treatment is also necessary, and mentions the change of opinion which has come over the medical world in regard to the relative importance of attention to the microbe in tuberculosis, as compared with the more important elements of the nutrition and hygienic condition of the patient.

If auto-intoxication is suspected he knows of no better intestinal antiseptic than benzo-naphthol, which is odourless and tasteless. He thinks all alcohols increase the itching, and should, as a rule, be avoided. If a microbicide is needed salicin is recommended. Unless diabetes is present he does not believe in restricting the diet. He does not find that sea air aggravates eczema in anything like the majority of cases. Woollen underclothing is said to act as an irritant in some cases, and silk, muslin, or linen should, he thinks, be substituted.

### THE IMPORTANCE OF THE X-RAYS AS A MEANS FOR THE EARLY DIAGNOSIS OF TUBERCULOSIS. (a)

By Dr. ESPINA Y CAPO,

Of the Royal Medical Academy of Madrid, Professor of Tuberculosis in the Provincial Hospital of Madrid; Inspector of Public Health, &c., &c.

My work comprises three parts: first, radioscapy; secondly, radiography; and thirdly, the technique of both in relation to tuberculosis. In the first part I shall speak of radioscapy in cases of sound and tuberculous lungs; in the second of the use of radiography in the different stages of the disease, whilst in the technical section I shall refer to the best method of obtaining the best results in both.

**RADIOSCOPY.**—Radioscapy as a means of diagnosis in tuberculosis has constituted, since its appearance in the clinical field, one of the means in which the greatest hopes have been placed, so much so that since the fourth congress on tuberculosis held in Paris, it has been considered the equal both of percussion, superficial and profound, and of auscultation.

In that fourth congress, however, we could not speak so affirmatively because we were not yet in possession of positive instances which would leave no room for doubt. To-day it is already impossible to detract from this potent means, admitted as such in all countries and by all practitioners.

Partisan as I am of the parasitic doctrine, I will not treat of the radiographic diagnosis of open pulmonary tuberculosis, because the analysis of sputum, and the presence in it of the bacillus of Koch, affirm so positively the existence of tuberculosis, that no physician can detract from this method. Radioscapy, in the case of open tuberculosis, serves only as a potent means of

(a) Abstract of paper read at Annual Meeting of British Medical Association, 1901.

(a) Abstract of paper read before the British Congress on Tuberculosis.

settling the topography of the lesions, and although this is very important, it does not deserve to fix our attention, because we prefer to employ our time studying the true use of X-Rays in the diagnosis of pulmonary tuberculosis in its first period full of doubts, and in which therapeutical intervention, being more rapid and convenient, is also more efficient.

There is another question of transcendent importance, in which the X Rays have assisted our investigation with such clearness, that this peculiar aspect of the question justifies our fixing it in our attention. I refer to glandular tuberculosis, the commencement, in many cases, of pulmonary tuberculosis, and in all the inseparable companion of the disease.

Apart from the data given by all authors in explanation of the changes of colour from which the radioscopic image of the lungs suffers in the incipient, settled, and cavernous stages, we shall not refer to them, because at this Congress we are obliged to present subjects of some novelty. I am going to mention, however, two circumstances, which, I believe, perhaps through ignorance, possess that peculiarity, and which we can only observe, especially one of them, by radioscopy.

Radioscopy constitutes a powerful means of studying the dynamic forces. It is not possible to see by radiography all the functions and all the movements that characterize each function. For this reason the normal physiology of, for example, a joint during the different phenomena which constitute movement and action, can alone be seen on the fluoroscopic screen, an impossibility with the radiographic plate.

The two phenomena to which we are about to refer appertain to actions of an organ in a state of movement, and for that reason can only be observed by radioscopy. The first is the heart. Ever since Wells drew attention to the diagnostic value of tachycardia, all specialists and those who devote themselves specially to the study of tuberculosis, have set great store upon this datum, raising it to an important position in the early diagnosis of tuberculosis. One of the most efficient means of verifying this datum is by fluoroscopy. As we never lose sight of this diagnostical resource in our department of tuberculosis, we can affirm, in an indubitable manner, that, with the fluoroscopic screen, the datum of Wells is seen in more than 94 per cent. of cases of tuberculosis with so much clearness as to remove all doubt on this subject. I shall, moreover, refer to a sign which, I think, has not been touched upon by other authors, namely, that this tachycardia is not rhythmical. There is another sign in the heart of the tuberculous, but we shall study it when we treat of radiography.

The second example that may be taken for radioscopy, being essentially functional, and one which we have not seen referred to by any other author, appears to our observation with as much, or even more, constancy than tachycardia. We refer to the visibility of the diaphragmatic excursion, both in inspiration and expiration, a phenomenon that, as is easily understood, can be appreciated neither by common means of exploration nor by radiography. This phenomenon, which under normal conditions is rhythmical and symmetrical on both sides, in tuberculosis is neither rhythmical nor symmetrical. We have observed that in the tuberculous the diaphragm does not rise to the same height on the sick as on the healthy side, and that when the two lungs are affected the ascension is shorter on the worst side; in such manner, in the case of a tuberculous patient whose diaphragm on one side has no ascension or where it is very short, we deduce from this the correspondingly greater impermeability of the lungs.

Accepting also in the case of radiography of tuberculous lungs, as much as we have related respecting the several degrees of transparency and depth of shadows in the first stages, darkness in the tract of the ganglionic and lymphatic vessels, opacity in the congested lung, and very great transparency of the caverns, we shall only say with regard to radiography that it is possible with it to discover the data, also of a certain novelty, in the radiogram of the tuberculous.

In our remarks on tachycardia when dealing with radiography, we said that the heart gives a sign easier

of record by radiography than radioscopy. Since the adoption of this valuable means of diagnosis, the small size of the tuberculous heart has attracted our attention, being a true cardiac atrophy. If this, as we believe, is a positive indication of tuberculosis, we shall arrive at a definitive early diagnosis with greater ease if we find in our radioscopic and radiographic explorations small heart, especially if the investigations are accompanied by tachycardia; moreover, we have an explanation of the relations existing between the smallness of the heart, aortic narrowness, and the frequency of tuberculosis in such subjects, which determine the rule existing among these phenomena.

Another datum that may be observed is the peculiar shape of the intercostal spaces. In other works relative to the same matter, we have referred to the difficulty of performing percussion on tuberculous patients. The causes of this difficulty are two: the first the extreme narrowness of the intercostal spaces, it being impossible to place the fingers between the ribs, and the second the conical form of the tuberculous thorax. Now before the appearance of the Röntgen method we could hardly understand these difficulties, but since the clinical adoption of this new system, the reasons become apparent. In the radioscopic image is observed a disposition of the ribs strongly resembling the peculiar arrangement of roof tiles, in such a manner that the superior rib almost touches the anterior face of the inferior rib, the intercostal space being so small, particularly from the fourth rib downwards, that it is difficult to place the finger upon which percussion is made. With radioscopy this disposition of the ribs is very clear, and functional phenomena corresponding to the diminution of the respiratory excursion in the tuberculous impossible to diagnosis in any other manner, is very evident. As we see, radiography permits us to know data of transcendent importance in the life, in the functional, in the active, and for this reason it is not possible to rescind from this recourse in the diagnosis of tuberculosis.

The transient nature of the radioscopic image, and the necessity of taking it permanently, emphasises the need of closely following with radiography the datum described in radioscopy. It is true that radiography cannot give us any data of function, but in exchange, with this second method, anatomical facts remain permanently indelible, as a book ever open to study.

Amongst the most interesting facts that we can select from our experience in radiography are the deformities of the bones characteristic of tuberculous thorax. There are in the thorax certain bones, which for their bearing on respiration and also from the muscles that originate from them, are organs of transcendent importance in the osseous respiratory apparatus. They are the clavicle and the scapula. Their position, form and size also produce very important modification in tuberculosis.

In taking a radiograph of a tuberculous subject, we see the modifications of these bones; the clavicle principally presents an augmentation on the inflection of its external extremity, and resembling a hyperplasia, but without being sufficient to constitute an alteration of the tuberculous epiphysis, takes the shape of the head of a mace. The scapulas are higher, and the internal and superior vortex is more elevated, swinging towards the centre the point and internal edge which are raised on account of the peculiar disposition of the ribs and spinal column.

Without entering into the pathological physiology of these facts, which entirely depends upon the great respiratory necessities of the tuberculous, united with the reduction of their respiratory field, we must remark that radiography shows these pathological heteromorphics with great clearness. The roof-tile disposition of the ribs, of which we have spoken before in speaking of radioscopy, can be seen in an evident and clear manner by radiography. Besides these deformities of the skeleton, radiography also shows us the small size of the heart. Respecting this organ radiography has achieved wonders, not alone in tuberculosis, but as to its real situation; but putting aside this latter fact, and circumscribing also those data which we can recognise in tuberculosis by the

heart, we shall mention two that have, we think, a certain novelty and importance.

The first is the greater extension of the heart towards the lines of Traube and Friedreich on the right side, this fact showing, in our opinion, a compensatory insufficiency of the tricuspid valve, and, for that reason, ventricular hypertrophy on the right side; the radiographic image of the tired heart in tuberculous persons thus acquires a strong resemblance to the image of the tired heart of the emphysematous. The second datum refers to the special form of the heart of the tuberculous persons which thus acquires a strong resemblance to the image of the tired heart of emphysematous. The second datum refers to the special form of the heart of the tuberculous, similar to the foot of a Chinese woman in its left ventricular border, remembering the growth of the deformed foot of the Chinese. Respecting the lungs the facts of the first, second, and third periods are so classic that we do not consider them worthy to occupy your attention: for our part they are simply confirmative of what we related in the fourth congress held in Paris.

**TECHNIQUE OF RADIOSCOPY!**—To observe the wonderful phenomena of radioscopy under the best conditions of visibility, complete darkness is necessary, suppressing it until the light is produced by the Röntgen tube: for this purpose we have had a special box constructed, to conceal the light completely, provided with a simple mechanism adaptable to any exploration that may be necessary.

Another trouble that must be got over is the difficulty of applying the fluoroscopic screen, which is commonly rigid and mounted in a frame. In this form the screen can, in tuberculous cases, only be applied upon the sternum or upon the internal edge of the scapula. It is known that in radiographic images size and intensity depend upon the distance between the part under observation and the surface of the screen, so that with rigid screens it is not possible to obtain a corresponding equality of definition and intensity over all the surface, and to obtain such a result it is necessary to use a flexible screen mounted on card-board in such a manner that it can be adapted to the convexities of the thorax. One of our colleagues, a very competent person in these matters, Doctor Redondo, Fleet Surgeon of the Spanish navy, advises the employment in radioscopy, as a radioscopic screen of the strengthening screen whose image resembles in depth of tone the radiographic image, and gives as fine detail as the ordinary fluoroscopic screen.

This application of the strengthening screen makes the solution of the problem easy, because it avoids having to change in the laboratory the fluoroscopic material of which, as we have said before, the rigid screen is constructed.

This last modification of the fluoroscopic technique is relative to the examination of patients that must have fasted previously, to have obtained with more clearness the semi-lunar space of Traube, and to observe with greater ease the phenomenon of the diaphragmatic excursion previously referred to.

**RADIOGRAPHICAL TECHNIQUE.**—For some time we have omitted as much as possible the use of strengthening screens. This is not the moment to analyse in detail their advantage or inconvenience. I will refer, however, to one amongst its inconveniences which, I think, is pertinent at this moment, viz., the turbid and disseminated nature of the image. When, therefore, we treat of images that require great detail, obtained in subjects capable of enduring the exposure—a very short time—that is required to-day to obtain a radiograph, we refer to work without a strengthening screen in order to obtain a completely clean image, with richness of detail, especially in pleurisies and patients with but small caverns.

Another interesting subject in radiographical technique, that also gives clearness to the image, and richness of details, is the distance that should exist between the tube and the plate. Without discussing theory, but confining ourselves to the collected facts, we have succeeded in fixing this distance at 50 centimetres

from the thorax, at which we obtain the maximum richness of detail.

The last matter that will occupy us in this address, refers to the development of radiographic plates. We have tried nearly all modern and antique developers, from the iron classic and pyrogallic acid to diamido-phenol and diamido-resorcine, and from this study we have deduced the necessity of never developing in radiography with old liquids in any one proportion, as much with the developing as with the fixing agents; we use the diamido-phenol to 1·2 per 100, with sulphite of soda crystallised to 6 per 100 as a developer, and Enckel's (Swiss) hyposulphite to 25 per 100. With these products we make our baths instantly, that is for two or three radiographs only, especially in Madrid, where the purity of the Lazoya's water (4" hydrotrimetrics) permits of its employment in all photographic laboratories.

We finish, as we began, confident of having defined nothing either good or new; but the call of duty has bade us contribute our feeble forces to this concourse in which every altruism has its place in the fight with this dreadful tuberculosis.

## THE TREATMENT OF TUBERCULOSIS BY UREA. (a)

By ARTHUR H. BUCH, F.R.C.S.,  
Assistant Surgeon, Sussex County Hospital.

It is, I take it, generally granted that the most important factors in dealing with any cure for tuberculosis are susceptibility and immunity. Jenner first recognised the importance of the immunity of a portion of the community to a particular disease, and eventually his labours have procured the immunity of the rest from that disease. It was not, however, till comparatively recently that the importance of his work was understood. All the great workers in this direction, whilst studying susceptibility and immunity, have tended to be drawn in one direction, and that is the preparation of antitoxins, by means of the injection of which into the human body we can either render such immune to, or modify an attack already begun, by the germ peculiar to each disease. These antitoxins have been prepared from the growth of the different organisms concerned, under various conditions, and the result is that the chemical substances which have been injected into the tissues of those to be protected are powerful alkaloids or toxalbumins differing chemically from any combinations hitherto demonstrated in our organisations.

Now this class of antitoxins has so far proved of greater value in acute specific fevers, such as diphtheria, small-pox, typhoid and bubonic plague, than has the corresponding antitoxin in tuberculosis. But tuberculosis differs in many other respects from acute specific fevers. The former is a chronic disease, the latter acute. The tubercle bacillus is one of the family of organisms which are termed infective granulomata, the latter belong to a class which produce their toxic effects in the body without the formation of new growth around them. The tubercle bacillus has an exceedingly wide distribution, that of the others is, comparatively speaking, extremely limited. Every one of us has been exposed, some constantly, to infection by tubercle; comparatively few have developed the disease; whereas of those who, being unprotected either by a special antitoxin or by a previous attack, are exposed to active infection by any of the acute specific fevers, I presume it is safe to say that the great majority would develop such.

In other words, by far the greater proportion of mankind provide a fit soil for the growth of the germs of acute specific fevers, whereas a small minority only are capable of harbouring and developing in their tissues the tubercle bacillus. The majority of us, therefore, possess in our systems some vito-chemical combination or condition which renders us immune to any ordinary dose of infection by the tubercle bacillus, and it follows that that combination or condition must be actively

(a) Abstract of paper read before the British Congress on Tuberculosis.

hostile to the bacillus, for we are all exposed to the infection.

This substance, or condition, therefore, whatever it may be, in contradistinction to the antitoxins, must be such as is neither harmful nor foreign to the human organism. It most probably exists in some in a greater degree than in others; but, in any case, if we could induce in the tissues of the susceptible some difference in metabolism so that this substance or condition was introduced into or manufactured in their systems, there can be no manner of doubt but that we should rid the human race of tuberculosis.

It was by the observation that in his experience the gouty were particularly immune to tubercle that induced Dr. Harper, of Nottingham, to prescribe pure urea to the tuberculous with a view to increasing the amount of urea and uric acid in their systems, and it is because of the enormous importance that I believe attaches to this treatment that I am reading this paper.

Dr. Harper has published two papers full of interest in the *Lancet* this year (March 9th and June 15th), in which he mentions many cases of phthisis which, being apparently incurable, have recovered. I would draw attention to the fact that he was induced to try this treatment by the observation of the peculiar immunity of a small part of the community, namely, the gouty, to tuberculosis; in other words, for reasons similar to those which induced Jenner to try vaccination for small-pox. It is an extremely interesting fact to note that urea, in the shape of urine, has been taken from time immemorial as a medicine, and that the natives of India are at present using it in this way.

As the treatment is still on trial and in its infancy, the answer to the second must necessarily be uncertain. The following facts, however, will, I believe, be found to have a bearing on the case. Urea is one of the end products of nitrogenous metabolism, i.e., of the oxidation or reduction of proteid matter, and the medium in which most of the nitrogen excreted from the body is carried away in the urine.

Urea is formed, according to our latest knowledge, in the spleen, lymph and secreting glands, but principally by the liver. The original source of the nitrogenous matter, which eventually supplies urea, is, of course, the proteids consumed as foods.

It is evidently impossible at present to understand precisely why and how urea can act beneficially in tuberculosis, or what changes exactly take place on its re-entrance into the body. Urea contains nitrogen, as do these all important proteid matters. During the period of growth and development less nitrogen is eliminated from the body than during the decline of life. The balance of nitrogen, therefore, with absorption at one end of the scale and elimination at the other, plays an important part in the cell activity and vito-chemical constitution of the body. If we can prove that urea splits up during the process of absorption, and that its nitrogen is assimilated, it can only be assimilated in the metabolism of protoplasm. We shall then have established the curious fact that an apparently waste product, the result of a process of reduction by oxidation of protoplasm, on being passed through the mill, so to speak, a second time, assists in building up tissues similar to those from which it originally derived. The proof that urea is decomposed in the process of absorption and assimilation, and that its nitrogen is wholly or in part retained in the body, can only be ascertained with certainty by elaborate processes of analysis. With the general practitioner this is, as a rule, impossible, owing to lack of experience, time, and apparatus. But more experiments, including estimation of total nitrogen eliminated, will be necessary before definite statements can be made. Dr. Harper mentions in his paper that the urea in most cases is not increased.

A short description of some cases which I have treated in this way is as follows:—

CASE 1.—Man, *æt.* 36. Was deserted as an infant, and suffered from tuberculous disease of left ankle and

performed below the knee for the ankle joint disease, and double arthroctomy of elbows at age of ten to eleven. Twelve years ago lupus commenced in nostrils and spread with some rapidity to face and forehead. In spite of various treatment the disease progressed, and the following was condition when on March 26th last I commenced treatment with urea. One large ulcer occupied an area, around which I will trace an imaginary line commencing at the centre of hair of forehead to a point half an inch above the outer end of each eyebrow, then inwards along the upper border of the eyebrows to a point above the root of the nose. The nasal bones had necrosed and come away, leaving a round hole leading into nasal cavity. Ulceration existed on both cheeks, and the left lower eyelid had gone. From the outer edge of the ulcer on one cheek to a corresponding point on the other measured six and a half inches. In the centre of the face was a bridge tissue, representing remains of the nose covered with epithelium. Below this was another irregular hole where had been the nostrils. Ulceration was present over the area where the upper lip had existed, most of this having disappeared. The edges of these large ulcers were very much raised, irregular nodules composed of chestnut-coloured apple-jelly-like matter, sharp cut towards the ulcer and gradually sloping down towards healthy skin. Some of the nodules stood three-sixteenths to a quarter of an inch above the level of the ulcer. Inside the nose one large cavity existed, the septum, part of the ethmoid and most of the turbinated bones having disappeared. The walls of this cavity were in a similar condition of ulceration to the external parts. The granulations over all the ulcers were unhealthy, and showed no signs of healing except at the parts most distant to the spreading edge. Here such attempts were very feeble. There was very much discharge of a thin, purulent character. So much collected in the naso-pharynx that the patient almost choked every morning before he could get rid of this. The general condition was poor and the man most miserable. Treatment was begun on March 25th, when 20 grs. urea t.d.s. was prescribed. By June 11th the nodules on temples had disappeared, and that on lip was disappearing. At the present time the forehead is practically healed, a small sore on the lip, owing to the local application not suiting it, formed, and has not yet healed again. The local application during the whole treatment was not changed, nor was patient's diet or way of living. His diet was chiefly potatoes, and had been for years. His mode of living was to keep in one room all day, and come out to sell papers in the evening.

CASE 2.—Man, *æt.* 30. Father died of phthisis. Nine years ago lupus commenced on right side of face, and gradually spread round to under chin, healing behind as it travelled, except at junction of lobule of ear with face. Four years ago left side of nose and face was attacked. The patient also developed strumous dacrylitis in second finger of right hand four years ago, this eventually healed with deformity, leaving a tuberculous dermatitis on back of right hand. June 24th. Urea grs. 30, t.d.s., was prescribed. The patches were then all raised and nodular and covered with scales and scabs, under which, on removal, was the jelly-like granulation tissue. The most marked patch was on the left side of nose, as big as half-a-crown. July 2nd. Very great improvement. The raised areas are level at the circumferences with surrounding skin, and are less red. Sensation in them has improved. The scabs are now limited to central part. Urea continued. July 9th. The skin, which was stiff and hard where it was affected, is getting pliable and softer. The patches of lupus are melting away. Patient is still under treatment.

CASE 3.—A man, *æt.* 22. Glands both groins began to swell a month ago. No apparent cause found. One gland on left, softening in centre, opened, and typical tuberculous caseous gland substance scraped out. Other glands enlarged, and on the right, one softened. Urea grs. 30 t.d.s., increased gradually to grs. 40 t.d.s. The patient, who looked poor and thin, rapidly improved, and the glands did remarkably well; the one that was first scraped out healed in three weeks, the other

at work in three weeks. Diet and general conditions fairly good.

CASE 4.—Woman, *æt.* 30, married. Family history of phthisis. Glands enlarged for fifteen years left side of neck. Operated on four years ago, and again by myself six months ago, when I removed glands from base of skull to clavicle. Recurred two months ago, just under angle of jaw, and when put on urea, there was a large mass of glands in this situation pushing out the skin and looking as if they must come through. After urea grs. 35 t.d.s. for six weeks, these glands have almost disappeared, and the woman is better in every respect. Still under treatment. Diet and conditions fair.

CASE 5.—Boy, *æt.* 15. History of phthisis. History of two months pain and weakness in right elbow. The joint was almost fixed at a right angle, and very painful. All the hollows were filled with typical soft tuberculous granulation tissue in the synovial membrane. Wasting of forearm half an inch. No history of injury. July 2nd.—After urea gr. xx t.d.s., and rest on a splint for ten days, patient was much improved. Could flex forearm, so that fingers could touch shoulder. Extension not so good. Pronation on arm and supination nearly perfect. All these movements done without pain. The swelling about the elbow was very much diminished. July 9th.—Swelling about elbow has disappeared altogether. Movements as before, but extension from full flexion to within forty-five degrees of full extension. Still under treatment. Diet and conditions fair. Urea 1·4 per cent. Average total quantity urine, 36 ozs.

CASE 6.—Girl, *æt.* 18. History of phthisis on mother's side. Lupus commenced two years ago in nostrils. Glands enlarged in both submaxillary regions and broke leaving ulcers. In the left nostril only the orifice could be seen, owing to granulations of jelly-like material and swelling of the parts. There was a typical patch of lupus about the left part of the upper lip and cheek. July 9th. After a month with urea grs. xxx. t.d.s. the left nostril can be examined with ease and the septum seen to be occupied by a healthy granulating ulcer. The lupus on the lip and cheek have all faded away, and the tuberculous ulcers in the submaxillary regions have healed. Patient under treatment. Diet and general conditions poor.

CASE 7.—Patient, *æt.* 22. Many enlarged glands on right side of neck, together with large tuberculous abscess under sterno-mastoid from the softening of one. The abscess was opened, washed out and stitched up, no drain being used. In six weeks' time, after an average dose of 30 grs. urea three times a day, the whole of these enlarged glands had entirely disappeared. There was a history of phthisis in this case, but diet and general conditions were very good.

In all other tuberculous cases in which I have given urea myself I am having, or have had, good results. Not a single untoward symptom has arisen; on the contrary, the action has evidently been in many cases that of a nervous tonic.

In conclusion, I will draw attention to the fact that Dr. Harper has already laid stress in the *Lancet* on the facts that the tubercle bacillus in the laboratory grows best on media that are of low nitrogenous value, and that in the lower animals it attacks the herbivorous rather than the carnivorous.

The cow is an interesting animal, from this point of view, as it is the animal more often attacked by tuberculosis than any other. Here we have a large amount of energy expended in procuring a sufficiency of nitrogen from herbs and a large loss daily in proportion in the casein of milk. This process of extraction of nitrogen goes on far beyond the ordinary period of lactation. It would seem that there may well be a relationship between nitrogenous absorption, assimilation, and elimination, and the tubercle bacillus in this case. I sincerely hope that elaborate experiments will be made with urea in the near future, and that it will be widely tried in all forms of tuberculosis. Personally, I believe that Dr. Harper's discovery will lead to a revolution in the treatment of this disease, and that many cases which have been considered hopeless in the past will be cured in the future.

## THE GENERAL MEDICAL COUNCIL.

### ADDRESSES BY THE CANDIDATES FOR THE NEXT ELECTION.

ADDRESSES by Mr. G. Brown, Dr. J. G. Glover, Mr. Victor Horsley, Mr. George Jackson, and Dr. S. Woodcock were delivered before a meeting convened by Dr. G. Horder which took place on August 2nd, by permission of the British Medical Association, at the Ladies' College, Cheltenham. The chair was occupied by Dr. Horder, who invited Mr. George Brown to speak first.

Mr. GEORGE BROWN said he did not regard the meeting as one that can come to any definite conclusion by way of deciding as to who should or should not be recommended to the constituency as those who should be selected for representation. He was not prepared to give an account of his stewardship then and there, but hoped that he had succeeded in satisfying those who had placed him in that position. Under these circumstances he hoped it would be agreeable to the medical men of England and Wales to give him their votes again. Having put his hand to the plough he had no intention of turning back, though, as a general practitioner, it was undoubtedly a great tax upon one's time. He had opposed the Midwives Bill for ten years on the principle that he did not believe that a partially educated woman after three months education should be given a diploma or licence to practice midwifery, and be allowed to use dangerous drugs which they are advised to do by those who lecture to them. At a meeting at Manchester he had said that if he remained on the Council for three years without something being done he would resign his seat. This he had not done because he found that their sending as direct representatives to the Council men from their own body had a considerable effect and influence on some important matters, for instance, more stringent regulations with regard to the suppression of unqualified practice. Since the last election much had been done by the Council in prohibiting unqualified assistants, and the effect of that had been of a most satisfactory kind as evidenced by the higher salaries that were obtained, and a great deal has been accomplished also in respect of preliminary education, although the effects were not very apparent yet, but the regulations are agreed to which will have a great influence indeed in the future admission of candidates to the medical profession. Referring to the case of the late Kingsley Hunter, he said that he could not acquit himself from all blame in that matter, but the fact was that Mr. Hunter's name was dovetailed in a list of unqualified men and no one knew that he possessed a qualification otherwise he would not have consented to his prosecution. He certainly thought they ought to have had a summary of the evidence, but then if he had applied for such he would have been told he was wasting the time of the Council as he had been told before. He complained that more than once when he had a motion down on the paper someone popped up and moved the previous question which unfortunately was invariably carried. That however did not occur now. He said that his colleague, Mr. Horsley, and himself had worked very harmoniously and happily together during the time we have been on the Council, and if he had the happiness and honour to again represent them on the Council he would have the opportunity of continuing to work with him. He hoped they would send three representatives who would work harmoniously hand in hand, because it weakened direct representation when one voted on one side and one on the other.

Mr. A. B. RITCHIE (Manchester) asked if Mr. George Brown believed it probable that the practice of midwives could be restricted by legislation, so as to make the attendance of a medical man compulsory in cases of confinement; also what policy did he support in connection with such legislation as was threatened?

Mr. GEORGE BROWN said he would oppose the present Bill *in toto*. He was in favour of a Bill for the better training of nurses by public bodies for poor people.

Mr. A. B. RITCHIE said that Mr. Brown had not answered his questions, and Mr. R. H. WOLSTENHOLE (Manchester) wanted to know if Mr. Brown supported the Medical Guild Scheme. To which Mr. G. BROWN replied that the scheme was on the lines that he would support.

Mr. J. S. WHITAKER (Great Yarmouth) said it would be more satisfactory if Mr. Brown answered Mr. Ritchie's question whether he believed that it was reasonable or possible to expect the Legislature to pass any measure requiring every obstetric case to be attended by a medical practitioner.

As Mr. George Brown did not quite understand the question in that direct way, the CHAIRMAN read out the question to Mr. Brown, who said that he was sure the Legislature would do nothing of the kind.

Dr. J. G. GLOVER expressed the hope that they would have at the next election a larger vote of the profession than on any previous occasion. It will be impossible to get any real addition to direct representation if three-fourths of the profession stand aloof and left the election to groups and small numbers. A very serious blow was inflicted on direct representation after the last election, when one of the gentlemen elected, after clamouring for a seat, left the Council without even waiting to discuss the main question he was supposed to understand, and for the solution of which he was chosen. He had enjoyed their confidence for fifteen years—that is, for three separate quinquennial periods—and he was asking them once more to re-elect him. He pointed out that few members of the Council had seen more of its working; few had had a larger experience of its principal committees; few knew better what the Council could do and what it could not do than himself. The Council was not perfect—it was too large; it wanted reconstruction, and it wanted larger powers; but in his opinion it had great powers for good even in its present form, and he saw no immediate chance of it being materially altered. It had done very much already and might do much more, both for the public and the profession—for medical education, and for the purity and dignity of the medical profession, which are of enormous consequence to the public. And he believed sincerely that for those ends the presence

on the Council of general practitioners—men acquainted with general practice, with its problems, its difficulties, its grievances—were essential and would be acceptable to the Council. Even those who differed from him on the matter of the midwives question would allow that I have never shirked the question, and that I had consistently held that some regulation of midwives' practice was urgently required, and could scarcely be had without legislation. His support will only be given to a Midwives' Bill on two or three very strict and well-defined conditions. First, that the practice of unlicensed midwives be stopped and penalised; and, secondly, that the midwife should be required, on the occurrence of any irregularity or abnormality of mother or child, to apply to a registered medical practitioner, thus placing her in a distinct, non-medical, subordinate position. He had a third condition, to which he attached much importance, though he had not been able here, as in the other points, to get the Medical Council to agree with him—viz., that the local sanitary authority of each district should be required to pay medical men a reasonable fee (not less than a guinea) when appealed to by the midwife. He wished to abolish the existing untrained, ignorant midwife—the Sarah Gamp—believing her to be dangerous and deadly to poor lying-in women, who are entitled to the greatest consideration; also to abolish the unauthorised function of the London Obstetrical Society in giving certificates to midwives. He was no party to blaming the Society for its efforts to raise the character of midwives and to give them some training, and he was quite sure that the Medical Council would find itself without public support if it sought to abolish this function of the Society, without seeing how the function was to be assigned to some other body. The only way, and the proper way, to get rid of the irregular and unauthorised action of the London Obstetrical Society would be to create a Board, acting under law, to do what it is doing, and for which it has in time past had the approval of the public and the tacit approval of the Medical Council. He felt convinced that such legislation would come to pass, and that it would be done independently of the medical profession if it loses the chance of shaping it and controlling and regulating the practice of midwives. In this matter as in some others, Mr. Brown had posed as the saviour of the medical profession. He has a medical paper all to himself—which in the interval of elections underwent a sort of hibernation, and just before the great event, came to life again and demonstrated to its readers that he (the speaker) was the great sinner the Jonah—and that he (Mr. Brown) was the man to elect to represent the profession. Yet, during the last five years Mr. Brown had never once in all the midwifery discussions moved the Council to declare that it disapproved of all such attempts at legislation. But he led his followers to think that he was going to do so, and that some great change was going to occur. He (Dr. Glover) would warn them that such a change could occur without the Council stultifying itself. Mr. Brown would probably not get a seconder as had happened on a recent occasion. The midwives question after all was only one of a score or a hundred questions that have to be considered by the Medical Council, which was *par excellence* a Council of Medical Education, and this must have for its basis a sound preliminary education. He had tried to do his duty as their representative on this question, and in the very first Session after his election to the Council he had drawn attention to the want of practical teaching in clinical and therapeutical subjects and of examinations in such subjects. The defect was admitted; he was put on the Education Committee, and the resolution he had proposed had been fruitful of good. Passing on to another topic he said that the principle of a Conciliation Board had been approved by a Committee of the Council of the British Medical Association, and there was reason to hope much from the application of it in the improvement of the position and power of the medical profession in relation to the great Friendly Societies. The Council had to discourage degrading and unprofessional modes of promoting practice—especially advertising and touting. He had proposed a resolution meant to discourage these practices, which had been very effective where the evidence of such practices and of the doctor's knowledge of them was sufficient. One or two large insurance companies with medical aid business had given up the business, and several medical officers had resigned their positions under this clause. Mr. Brown moved the Council to something more drastic and did not get a seconder. Such conduct was of no service to the profession; it wasted the Council's time and money, and placed it in an undignified position. Dr. Glover then commented on the present position of the reform of death certificates, and deplored the friction between the Royal Colleges and the Council which he hoped soon to be settled. In regard to the finances of the Council he believed that with some reforms in the conduct of their discussions the ordinary income of the Council would still suffice to meet its expenditure, and he was therefore opposed to an annual tax. He defended the Council against the charge of inertia, observing that the changes which are taking place in the profession—in its curriculum—in its education—in the public estimate of it—and in the State estimate of it were enormous, and in some aspects serious. He asked them to remember that as regards the election it was not the Medical Council that was on its trial so much as direct representation itself.

Mr. VICTOR HORSLEY said he was hopeful that the meeting would be the precursor of many similar meetings, and that it would be a fixture at the annual meetings of the Association. With regard to his views on the midwifery question he still held that registration of existing and prospective midwives was necessary and should be insisted on by the Legislature. Their duty as members of the General Medical Council was to see as far as they could that the Government did not lend their support to any measure which did not embrace the essential points given in detail in the Minutes of the General Medical Council. He complained that although the General Medical Council was practically a sub-department of the Central Government, its head being the Privy Council, which was presided over by the Duke of Devonshire, the Privy Council had during the last ten months treated the General Medical Council with superlative contempt. They would find all the facts in the Minutes. It was ridiculous for them to consider that as a sub-department of the Government they could through their President, or through anyone else, influence the Privy Council pri-

vately. The only way to do it was through the voice of the profession. He believed that they would get this power, but in the meantime the General Medical Council was unable to do what it wished to do in the matter. He personally was responsible for endeavouring to send up a protest to the Privy Council against its behaviour towards them as its sub-department. Dr. MacAlister, however, opposed him, and succeeded very easily in persuading the Council, so that no protest was sent. Another instance of such contemptuous action on the part of the Privy Council occurred in respect of reciprocity of practice in Italy when the Privy Council passed an order entirely disregarding their views as a Council.

As regards the work of the Council in education the matter of the Colleges was really a very grave question. The step taken by the Royal Colleges was subversive of the present five years' curriculum and of the best interests of the medical profession, and it would ruin students' registration. The representative of the Royal College of Physicians, which body was tottering to financial ruin, did not hesitate to state in the Council, and his speech unfortunately made a most favourable impression on the Council as a whole, that he was willing to ruin students' registration simply to carry out the wishes of his College. He warned them not to enter into any compromise on this matter, for any yielding would lead to an irreparable injury to the medical profession. As regards preliminary professional education headway was being made in this matter by the Council itself, quite irrespective of this step taken by the Royal Colleges. The question of education was considered with that of the one-portal system. By the constitution of the General Medical Council it was unable to receive a scheme for the one-portal system, for the Council was composed of commercially competing bodies, and was thus really unfit to control medical education. He then discussed the necessity for a Medical Act Amendment Bill. They had swept away the men who were bitterly hostile to the profession. It has caused hard words and some misunderstanding, but the men had gone, and in their place they had a younger set of men, among them deans of medical schools who are keenly interested in general medical education. These men are men to whom one would appeal with reason, and the outlook for the Medical Act Amendment Bill is better. But the body of the General Medical Council consider that such a Bill should come from the British Medical Association, and he was willing to accept that position. He suggested that they should meet them, that the British Medical Association should go on with the work of the Parliamentary Bills Sub-Committee and bring to the General Medical Council the Bill that they asked for. In such a Bill the mention of unqualified practice should take first place, but as the price of the purchase of that, of course, the House of Commons will require what we also require, that the constitution of the Council shall be changed, and that it should be deprived of its corporate body, that is to say its commercial character, so that it shall be made a representative Council, and if the House of Commons demanded it there should be an addition of one or two more Crown members. There must be a bargain, and they must give something in return if they were to get anything out of the House of Commons. He had left his next point to the last because he believed it was a ever by means of which they would reform the General Medical Council, viz., the question of money, which is at the bottom of most things. They had now got to the bottom of the pocket of the Council, and the Council was in a bad way and might find it necessary to go to the House of Commons and ask for some change in legislation which it could put into operation in order that it may live. He reviewed his action in exposing the unsoundness of the Council's finances and said that the report proposed as reforms everything that they had been asking for. Among these reforms was the Annual Registration fee. He said that he was a firm believer that the annual registration was a necessity in legislation. An annual registration fee of one pound would give the General Medical Council an income of £30,000 and that was amply sufficient for the Council to be really operative in the interests of the public and the profession. The question of the annual registration fee, which he personally considered a necessity, had never been properly discussed, and as they looked to Manchester as usual for reform, so they looked to the meeting at Manchester to have that point thoroughly threshed out so that we shall know what is the voice of the profession in the matter.

Mr. GEORGE JACKSON (Plymouth) recalled that at a previous election he had polled over 4,000 votes, and had been asked by the Incorporated Practitioners' Association to come forward as a candidate again. In regard to the question of the midwives he said they ought to try and guide legislation so that it shall not be registration of midwives as midwives, but rather as nurses, and I would say that all nurses should be registered. It should be impossible for any woman after just three months training to be turned out as a midwife. He urged that district nurses should be appointed who might give lessons in elementary sanitation and attend to ordinary dressings. The population was not increasing and one woman in fifteen was said to die in her first confinement. At any rate, the mortality was very considerable, and it behooved them to take more care of their population-producing people, to take more care of the mothers of the country and not allow them to die in this way, and to take more care of the children. He suggested that the British Medical Association should introduce a Bill into Parliament on the lines indicated on the "Medical Guild Quarterly," and that there should be a regular system of nurses that should have two to three years training before they were allowed to have anything to do with nursing, as a sufficient training was necessary so as to thoroughly drill the nurses in their work, because, if taught only for a limited time, the nurses relapsed into careless ways. He would be in favour of more direct representatives and of cutting up the country into smaller districts. The General Medical Council would thus be able to promote legislation favourable to the profession and to the country at large. Quacks, who practised under the name of aurists, oculists, should be prosecuted. It would be a good plan if every medical man had to pay a small annual sum each year which would then enable the Council to act. The examination for the entrance to the medical profession should be raised. Another important point is that a bill should be introduced into Parliament for the better registration of deaths, because of the enormous

number of uncertified deaths. Still, births also should be registered. He could not claim personal experience like the present representatives, but, if elected, he would carry out the duties as far as he could.

Dr. S. WOODCOCK, J.P. (Manchester), seemed doubtful whether or not he spoke as a candidate. He maintained that they were entitled to a representative from the north of England, and other places than London should have some share in representation. With regard to the midwives' question he had never been in favour of initiating legislation on this question. He objected to self-elected men arrogating to themselves the right of giving certificates to women, and he had assisted in elaborating a Bill in which two or three principal things were aimed at, limiting the function of the registered midwifery nurse in a definite way. This Bill, however, was to be put in only in order that it should not be said that they had nothing to suggest. He considered that to insist on a medical man being called in in every case of confinement was impracticable. With regard to the attitude of the present Government he said that with all their efforts they had never been able to get at the President of the Privy Council, who had invariably refused to receive a deputation. On the other hand, the promoters of the Midwives Bill had had no difficulty, and they were encouraged by him to go on, and when a vacancy occurred in the General Medical Council of a Crown nominee the appointment was given to the man through whose efforts more than anybody else the first and the worst Registration Bill was brought forward. With regard to the Medical Guild Bill, he did not disapprove of it, but he wanted something to be done in his lifetime. Speaking generally he approved of the attitude and policy of Mr. Horsley, and he agreed with him on this midwives' question. He was not supporting the measure in favour of the registration of midwives. He had also taken some part in attempting to draft a Medical Act Amendments Bill, and there he had sufficiently indicated his opinion in regard to the representatives of the corporate bodies. These should be elected by the licentiates and members of those bodies. He thought they should aim at having the one-portal system. If the Council was paralysed for funds we should go to Parliament and get permission to have an annual registration fee. He knew something of the work of general practice, and had had some experience in public life, and if the medical profession thought he had the ability and the tact to represent them sufficiently well he was prepared to place himself at their service.

Mr. BIRCHIE said after the speeches they had heard the midwives question must be dropped out of that election.

Mr. G. H. BROADBENT (Manchester) said that he thought just the opposite because it was most essential.

The CHAIRMAN then asked the candidates: Did they believe it probable that the practice of midwives will be restricted by legislation so as to make the attendance of a medical man compulsory in cases of confinement, to which they answered, No.

Dr. GLOVER said in reply to Mr. A. Cox, of Gateshead, that he voted for the present form of certificate issued by the London Obstetrical Society, and he would continue his present attitude until some legal body was provided to look after that business.

Dr. MAJOR GREENWOOD remarked that the Council had made the Obstetrical Society alter the diploma issued to midwives into a certificate. What was it that led those who held certificates to go on using the term L.O.S. That was the most important point and that was omitted by the Council.

Mr. WOLSTENHOLME asked Dr. GLOVER if he had afforded Mr. Horsley assistance when the Chairman of the Council refused Mr. Horsley access to the documents.

Dr. GLOVER said that he did not remember the circumstances about the first resolution dealing with the documents. The ultimate resolution, however, by which the documents were accessible, was moved by him. He explained that he had no other object than to secure first the care of the documents, and secondly, the right and convenience of members in the use of them. The present resolution of the Council was drawn up by him in place of the first one, which, though he supported, was not quite satisfactory.

Dr. WOLSTENHOLME said the scheme of the Royal Colleges appeared to reduce the medical curriculum to four years. Dr. Glover had spoken of a *modus vivendi*, was that to prevent the five years' course being cut down to four?

Dr. GLOVER replied that he had no intention of disturbing the five years' course, and there was not one instance in which the Colleges had accepted less than a five years curriculum. They included in that curriculum one year passed at a preliminary educational institution approved by them.

Mr. WOLSTENHOLME then wanted to know if Dr. Glover agreed to that.

Dr. GLOVER said that he agreed with that till the Council had power to interfere with the legal rights of the Colleges.

Mr. WOLSTENHOLME then demanded from Mr. Horsley whether he had had any difficulty in inspecting the documents of the Council, whether he had been thwarted in that attempt, and whether Dr. Glover had properly supported him. Also was Mr. Horsley in favour of the *modus vivendi*.

Mr. HORSLEY: In regard to the first Session when the question of the documents came up, he saw when he made his protest he was opposed by Dr. Glover so strongly that actually he could not obtain a fair hearing, and during the whole of that week's work he was looked upon as a kind of outcast for having endeavoured to disorderly interrupt the Chairman. That was the state of affairs, but he carried his point at the next Session. He admitted that it was on Dr. Glover's motion that the documents are now open for inspection. With regard to the *modus vivendi* with the Colleges, he thought that if the matter were brought before the Courts the Courts would have to say both parties were in the right, so he intended to resist any attempt to spend the money of the profession in going to law in this matter. There is no possible *modus vivendi*. If the Council chose to succumb to the Colleges, that was possible, and unless the direct representatives would say, with the voice of the profession behind them, that the Council shall adhere to its former position, a very grave injury would be done to the medical profession.

After some further questions and remarks, the proceedings terminated with a vote of thanks to the Chairman.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 10th, 1901.

### SANGUINAL KREWEL.

A PARTICULAR mania for new drugs with physical and chemical demonstrations has now overtaken the minds of the Austrian medical world. Diagnosis and prognosis was formerly the chief end of all medical labour in the wards with bacterial examination to confirm the prophecies, and there the case ended. Now things have changed. In every ward you enter experiments are proceeding with some new drug which has given rise to a restlessness for novelty which is constantly supplied by the proprietary vendor, who is ever ready to act on the slightest suggestion.

Sanguinal krewel is another of those hæmatic preparations recently launched on the market as a ferri albuminous combination. It contains the iron in its native form, and represents 10 per cent. of hæmoglobin, 44 per cent. of peptonised muscle, and 46 per cent. of the blood salts which Bunge affirms is the most important constituent to be supplied in all cases of anæmia.

Gerber, in Prof. Neusser's wards, has recently been testing the efficacy of sanguinal krewel in chlorosis as a standard test for anæmia. Many experiments have been conducted with it in neurasthenia, rachitis, scrofula, nephritis, tuberculosis, and syphilis with the greatest success, but in chlorosis, where Boerhave has affirmed that "*Nihil in hoc casu plus conducit quam Chalybis*" has not authoritatively been put on record, which Gerber has endeavoured to supply. He affirms that he has not attempted to interfere with the question still under controversy, whether iron supplies a want or merely stimulates the hæmato-potic apparatus, but contents himself with the physiological and clinical results with actual examinations of the blood. No effort was made to discover whether the albuminoid compound was broken up as a chloride sulphate or nitrate, as it is now taken for established that the drug is absorbed as an albuminoid. In addition to this sanguinal krewel combines in itself the constituents of the other theory that the salts of the blood are at fault, which is supported by the fact that manganese and fresh peptonised muscles, which alone is potent in the regeneration of nuclein, lecithin and fat are all present, thus increasing the number of the red blood corpuscles and amount of hæmoglobin in the sanguineous fluid.

In all the cases experimented on the clinical facts, both objective and subjective, were excellent. The body weight and general appearance was improved, while the dyspnoea and palpitation were removed in a very short time.

To prove this he quotes the case of a young woman, æt. 20, factory worker, who had suffered for three years from chlorosis, for which she had used Blaud's pill, ferrum, &c., with varying degrees of success. Still she complained of general malaise, difficulty in breathing, rigors, palpitation, pain at the cardiac end of the stomach, menses irregular, and dysmenorrhœa.

On February 10th pil sanguinal, three per day, was administered. Hæmoglobin, 80 per cent.; red blood corpuscles, 24,80,000; colour index, 0.4; white cor-

pucles, 4,320; body weight, 52½ kilos, or 115.5 lbs.; poikilocytosis, microcytosis, and blood-plates.

On March 17th the hæmoglobin was 60 per cent.; red blood corpuscles, 5,240,000; colour index, 0.6; white blood corpuscles, 4,800; body weight, 55½ kilos, or 121.2 lbs.

The second case was a housemaid, æt. 16, who for the last half year had suffered from severe headache, difficulty in breathing, vertigo, rushing in the ears, constipation, and pain in the stomach. The skin and mucous membrane were pale; systolic murmurs over mitral and pulmonary areas; cardiac area diminished; spleen imperceptible, no fever, no albumin in urine or œdema anywhere.

On February 25th 25 per cent. hæmoglobin, red blood corpuscles, 2,287,000; colour index, 0.6; white blood corpuscles, 6,400; body weight, 54 kilos. After commencing with three pills of sanguinal it was increased to four pills a day on March 4th, and on March 26th the hæmoglobin was 45 per cent.; red blood corpuscles, 4,200,000; colour index, 0.6; white corpuscles, 5,960; body weight, 58 kilos, or 127 lbs.; while the blood corpuscle as in the former case had resumed a normal appearance.

Fifteen other cases related gave somewhat similar results, which speaks favourably for sanguinal krewel as a hæmapoetic drug.

#### HOFBATH BARON WIEDERHOFER.

Another of Vienna's lights have ceased to burn in the person of Professor Wiederhofer, who has long enjoyed the imperial sunshine of the palace, being the favoured attendant and special adviser in the Imperial family.

He was born at Weyer, in Ems, Upper Austria, 1832, and qualified in medicine at Vienna in 1856. He commenced as assistant under Professor Mayer, in the Children's Hospital, and soon after was appointed second in the Vienna Orphanage. In 1862 he was made extraordinary professor, and in 1884 ordinary professor.

It was in 1863 he was appointed private attendant to the Kaiser's family, since which he has endeared himself to the head of the monarchy in Austria.

As teacher and examiner, Wiederhofer was respected as a highly-cultivated and learned authority in pædiatrics. Students and colleagues were regularly found crowding his class-room, which was never large enough for the number that desired places.

Two years ago he was seized with an apoplectic fit, from which he recovered, but last winter another repetition paralysed the centre of speech. To recover strength he was transferred to Ischl, where he died, under the solicitous care of the Kaiser and his family.

### KING'S COLLEGE HOSPITAL.

EXCISION OF LOWER JAW FOR SARCOMA (?).—Mr. CARELESS operated on a girl, æt. 21, who had been the subject of a large swelling of the right side of the mandible for some months. The case had been under the care of Dr. Bateman, of Richmond, and the tumour had increased considerably. Dr. Bateman had previously made an exploratory incision demonstrating that the mass was mainly solid, but with bony foci scattered through it, and that it was exceedingly vascular.

The mass had grown since that exploration, but not very rapidly; it was of a hard consistence, but it felt more like cartilage than bone, there being a slight "give" about it; the margins were very sharply defined, and the mass projected mainly on the outer side, encroaching but little on the mouth. Mr. Carless expressed the opinion that the tumour was of a fibro-cystic type, or, as it has been termed by Mr. Bland-Sutton, an epithelial odontome. The patient having been anaesthetised, an incision was made from the lobule of the ear behind the tumour mass to a point half an inch behind and external to the symphysis menti, practically running along the lower border of the jaw. In the centre this cut was deepened so as to expose the tumour; the fibres of the masseter were firmly incorporated with the outer wall, which was opened through, exposing a tumour mass partly infiltrated with bone, and exceedingly vascular. The finger was used to break down the mass and define its structure and limits, and as it was found that the growth occupied nearly the whole of the vertical ramus, and also the horizontal ramus as far forwards as the second molar, it was obvious the only way to deal with it was to excise this portion of the mandible. The cheek tissues were therefore reflected off the outer wall of the tumour, but the greater portion of the masseter had to be left attached to it. The horizontal ramus was cleared and a section made with the saw between the first and second molar teeth. It was subsequently found that the inner aspect of the jaw had been slightly encroached on by the tumour in front of this line, therefore a second section was made immediately behind the canine tooth. The tumour mass was then enucleated; this was a matter of some difficulty owing partly to the hæmorrhage, partly to the fact that the mass broke down, the outer portion of it breaking away with a part of the horizontal ramus, leaving behind a deep soft portion, which extended into the pterygoid region and upwards, along the temporal tendon as far as the great wing of the sphenoid. Both the coronoid process and condyle were removed, the growth having encroached to within a very short distance of them. The whole dissection was made with a very small opening in the mouth, really not more than three-quarters of an inch, as a number of the teeth on that side had been removed previously. The bleeding having been stopped, an attempt was made to close the wound in the mucous membrane by the introduction of stitches, and the external wound was sutured in the usual way, a drainage tube being left in. The tumour was as large as a good sized orange, and it had destroyed the greater portion of the jaw. The slowness of the growth and the sharp definition of its borders were points in favour of its being simple and not malignant in nature. Mr. Carless emphasised the desirability of not laying the buccal cavity more freely open than was possible, inasmuch as by this means it was easier to prevent the wound becoming septic; suturing up the mucous membrane, he said, also had this object in view. Unfortunately this happy result was not attained as the wound subsequently became infected, but not seriously.

### TOTTENHAM HOSPITAL.

HYSTERECTOMY FOR MYOMA.—Dr. ARTHUR GILES operated on a single woman, æt. about 40, who had suffered for some time from pressure symptoms due to the presence of a large uterine myoma. Dr. Giles had

performed an operation for myoma uteri on the patient's sister three years ago. In the present case the patient was seen about two months before the operation, when she complained of pelvic pain, frequency of micturition, and menorrhagia. The last symptom was not, however, very pronounced. On examination the cavity of the pelvis was found occupied by a hard large mass which depressed the pouch of Douglas and extended laterally, so that it appeared to invade both broad ligaments. The cervix was drawn high up behind the pubes, and there was scarcely room for the examining finger in the vagina between the tumour behind and the pubes in front. In view of the form of the tumour as felt through the vagina, and of the fact that hæmorrhage was not a conspicuous feature in the case, it was surmised that the growth was mainly sub-peritoneal with lateral extensions into the broad ligaments. Operation was advised on account of the pressure exercised by the swelling. The patient readily agreed to operation, but desired to wait until the reopening of the Chelsea Hospital for Women where her sister's operation had taken place. As there appeared to be no immediate urgency this was arranged. Some weeks later, however, she had retention of urine on several occasions, and it was decided to operate without delay. From the character of the growth as diagnosed a difficult operation was anticipated, but on opening the abdomen and raising the tumour out of the pelvis the operator was agreeably surprised to find that the cervix and broad ligaments were in no way involved, and the operation proved to be a simple and straightforward one, the ordinary supra-vaginal hysterectomy being performed. The main portion of the growth was the size of a foetal head, it originated from the posterior aspect of the fundus and had extended downwards in its growth till it had occupied practically the whole of the available space in the true pelvis of the cavity of which it formed a fairly perfect cast. A marked flattening of the left posterior border indicated the position of the rectum. The body of the uterus was studded anteriorly with several small growths resembling new potatoes, but its cavity had not become involved. In the toppling over backwards of the tumour the cervix had become gradually drawn up anteriorly. The frequency of micturition and the subsequent retention of urine from which the patient suffered were readily accounted for by the anatomical conditions present. Dr. Giles said that there were three leading indications for surgical intervention in cases of myoma:—1. Hæmorrhage; 2. Degenerative changes, and 3. Pressure symptoms. One or more of these might be present in the same case. In the present instance operation was undertaken on the third indication. It was evident, he pointed out, that had the case been left alone the pressure effects must have been grave; those most to be feared would have been changes in the bladder and kidneys; pain also must necessarily have become very severe. Diagnosis of the precise condition present was practically impossible, as the pelvis was so completely filled up; the subperitoneal character of the growth was indeed suspected on the grounds given before the operation, but the important matter from the point of view of operative manipulation, whether or not the lower zone of the uterus and the broad ligaments were free from growth, could only be determined after the tumour was exposed. He called special attention to the

characteristic cast of the pelvis formed by the tumour, this, he said, was not often seen except in the case of cervical myomata.

WEDNESDAY, AUGUST 14, 1901.

### THE CHOICE OF DIRECT REPRESENTATIVES.

THE meeting at Cheltenham last week, of which we publish a report elsewhere, brings the approaching election of direct representatives to the fore. We commend this report to the notice of our readers, at any rate of those who are interested in the election of representatives for England. From it they may glean an idea of the present condition of medical politics, and form an opinion as to the points to be borne in mind in voting for candidates to represent them on the General Medical Council when the present mandates have expired by effluxion of time. There seems to be a general opinion that the time has come for the infusion of new blood. Although there are obvious advantages in selecting men who are closely in touch with the wants and aspirations of the great mass of general practitioners, that is to say, men who are themselves general practitioners, this alone should not be deemed a sufficient qualification for selection. It is necessary that the direct representative should be in a position to command attention and respect, either in virtue of his professional status or by reason of his intelligence and familiarity with the problems in the solution of which he will have to take a more or less prominent part. Mere amiability of character and affability, though they may conduce to harmonious relations with the other members of Council, are not qualities calculated to the effective discharge of the responsible duties which the direct representative is required to discharge. Then, too, the representative should be a man of superior education, in order that he may hold his own in a society of educated gentlemen. In so far as these

qualities, or the more desirable among them, are common to all the candidates some further test must be applied. Clearly it would not be prudent at the present juncture to make the much-debated midwives' legislation the touchstone. There is reason to suppose that the general feeling in the profession is opposed to legislation in the direction of providing for the registration of midwives, and this feeling, no doubt, is mainly influenced by the view that to dub midwives women who have received at most a very perfunctory training in the art is to invite, nay, to create, a detestable form of competition. Nevertheless, it is well to recognise that something has to be done, and the most becoming, as well as the most tactful, attitude for medical men to adopt would be to use their influence to secure the introduction of clauses providing for adequate medical control. By opposing legislative proposals tooth and nail, without presenting alternative proposals, we should simply play into the hands of those who foster the measure, especially as the latter have the advantage of Government support. But there are many other questions before the profession which require to be dealt with. There is the question of Council reform, as to which we must require very explicit assurances on the part of candidates. It is idle to clamour for additional direct representation so long as not more than a fraction of voters take the trouble to avail themselves of the privilege of voting; but we do want the Council to take a wider view of its duties towards the profession and to obtain such additional powers as may be required to enable it to fulfil its functions in purifying the *Register*, and in suppressing the irregular practice of medicine. The finances of the Council are in a most unsatisfactory condition, and we are face to face with the necessity of providing additional funds, possibly by the imposition of an annual tax on registered practitioners. We agree with Mr. Horsley that such payment would in many ways add to the influence of the profession on the Council and of the Council on the public. Lastly, there is the question of the standard of preliminary education, which continues to furnish material for copious discussion without making much progress. The time is not yet ripe for us to discuss the merits of the individual candidates upon whose utterances we shall ponder.

#### "CHRONIC HARMLESS LUNATICS."

THE question as to how the numerous "chronic harmless lunatics," as they are officially termed, which are distributed through Irish workhouses, are to be provided for in a manner which will satisfy modern humanitarian and scientific ideas is one which at the present moment demands solution. Our readers will remember that the Irish Local Government Board issued a circular on February 26th of this year to the Irish County Councils in which they proposed that the latter should consider the following schemes, with the object of determining which would be the most suitable:—

1. To build a separate Auxiliary Asylum for

chronic harmless lunatics with a Resident Medical Superintendent, and at least one assistant medical officer.

2. To add, subject to the Lord Lieutenant's directions, by the erection of buildings less elaborate than the original ones, a new department to an existing Asylum, and to place it under the Resident Medical Superintendent of that Asylum.

3. To acquire and adapt some workhouse or other building, either as a separate Auxiliary Asylum, or, if the Lord Lieutenant should so direct, as a department of some existing Asylum.

The order of merit in which these three schemes will be placed by those who only consider the well-being of the insane, and by the County Councils will probably be very different, and in this opposition of views lies the great danger which awaits all efforts to solve the question of providing adequate accommodation for the chronic insane. If medical superintendents, and philanthropists generally, range themselves on one side, and county councillors on the other, and if neither of them consider that there is any force in the arguments of the other, then the County Council, who hold the purse strings, will carry out whatever scheme is cheapest. If, on the other hand, attempts are not made to force the County Councils into excessive expense, it will probably be found that the latter will agree to whatever scheme unites economy and efficiency. Proof of this is furnished by the action of the Committee of Management of the Down District Asylum and the County Council. In March last, a special joint committee was appointed by these bodies to consider the communication of the Local Government Board, and this committee recommended the adoption of scheme three. Thereupon, the Medical Superintendent addressed a circular letter to the members of the Committee of Management, in which he pointed out the expenses which such a scheme would entail, and the advantages of adding new buildings to the existing asylum—a scheme by which the chronic insane "would have the benefit of the exceptional surroundings of the present asylum, standing in grounds of 170 acres, and well equipped with all adjuncts required by the insane when living in association." And, he stated, further, "that the major portion of the outlay involved in locating the chronic lunatics within the asylum walls would, if his suggestions be adopted, go to render more efficacious those portions of the institution set apart for the acute and curable cases." The immediate result of this letter was that a fresh joint committee was appointed by the Committee of Management and the County Council, and that, at a meeting held in Belfast on July 19th, it was decided to rescind the resolution formerly adopted, and unanimously resolved to recommend the County Council to provide for the insane at present in the workhouses of the county by adding to the accommodation of the existing asylum. We congratulate the County Council on their decision, which in their case and in the case of many similarly situated asylums is at once

the most suitable and the most economical. In our present number we publish a paper by the Resident Medical Superintendent of the Down County Asylum, Dr. M. J. Nolan. In the course of his paper Dr. Nolan elaborates his proposals for dealing with those whom he terms "residual lunatics." At first, we confess, we identified Dr. Nolan's proposition with scheme two of the Local Government Board. This conclusion, however, was incorrect. Dr. Nolan's proposition in brief is as follows:—Transfer the "chronic harmless lunatics" which at present are in workhouses to the county asylum. If there is sufficient existing accommodation for the purpose, so much the better; if not, it must be provided. If there is no room for the extension of the present asylum build an off-shoot to it, not as an "auxiliary," but as "a legitimate branch of the same constitution." Each "chronic harmless lunatic" is then in a position to receive—not the two shilling grant of the auxiliary asylum, but the four shilling grant which is given in the case of the certified lunatic. Furthermore, the expense of the installation and maintenance of a completely new establishment is avoided. And, lastly, the "chronic harmless lunatic" is not condemned—because he is harmless and chronic—to a worse existence than is the acute dangerous lunatic.—Dr. Nolan's scheme at first sight appears to be practical and economical, if the difficulty of obtaining the full capitation grant is removed. It may be, that, "the Act of 1898, with one stroke has practically certified some 4,000 individuals of unsound mind, now located in workhouses . . . and provided that they may be removed elsewhere." Is, however, this certification of a sufficiently practical character to carry with it the full capitation grant of four shillings instead of the grant of two shillings per head which the Local Government Act specifies? That the amount of the latter is absurd few will deny, but it apparently is fixed by the Local Government Act. Here is an opportunity for the Irish members of Parliament.

#### WHAT IS A SANATORIUM?

PUBLIC opinion just now is all in favour of the provision of additional sanatorium accommodation for the phthisical. This wave of opinion has a solid foundation because it embodies the application of the *vis medicatrix naturæ*, but unless carefully supervised it may lead to very undesirable results. The present tendency is to raise a considerable amount of money and then to build a more or less gigantic, and in any event very costly, edifice, in which the unfortunate victims of tuberculosis are to be aggregated. Now there are numerous and weighty reasons why this plan should be modified. Administrative control of an institution of this kind increases out of proportion to its size and, from a bacteriological point of view, nothing could be less desirable than the concentration of large numbers of phthisical patients under one roof or on a limited area. Not only the

cost of construction but also the cost of maintenance increases out of all proportion to the increase of size, and the moral effect on the individual patient of living in the midst of a community of persons similarly afflicted, cannot fail to be the reverse of beneficial. If sanatoria are to be constructed by local authorities or by local philanthropic agencies in any sort of proportion to existing requirements, a much more economical plan will have to be followed. It happens too that economy in this matter is not incompatible with efficiency; indeed, we greatly question whether a multitude of smaller institutions would not on the whole be more beneficial and more easily compassed than a less number of more or less gigantic structures erected at an immense cost. The simplest form, one moreover which is available for many months in the year, is the camp sanatorium. Under intelligent management these could be made and kept as hygienic as the larger buildings; indeed, the problem of complying with sanitary requirements is necessarily much simpler when we are dealing with a comparatively small number of patients than when they are counted by hundreds. There is one point in respect of which, at first sight, the large establishments may appear to offer an advantage, *viz.*, medical supervision. But is this really as important as one is apt to suppose? Except in advanced cases the general principles of treatment are pretty well stereotyped, and can be formulated at the time when the patient is sent to the sanatorium. Obviously such camps must be within a reasonable distance of medical aid, and it might even be well to arrange for daily visits by a neighbouring practitioner who is willing to master the principles of this treatment. If a patient is so ill as to require close medical supervision his place is elsewhere than at a sanatorium, at any rate at a sanatorium of the class under consideration. The fact that the open-air treatment can be made available at comparatively small cost is one which cannot be made too widely known. The number of persons actually suffering from pulmonary tuberculosis is enormous. One of the fundamental principles enunciated at the Congress which has just taken place was that the removal of consumptives belonging to the labouring classes from their insanitary surroundings is indispensable to any success in the endeavour to stem the tide of contagion. Not only is the patient himself placed under conditions favourable to recovery, but by removing him we remove a fertile source of infection from his family, his neighbours, and from the district in which he resides. At the sanatorium he will learn enough of the nature of his disease to recognise and adopt the elementary precautions which, if methodically carried out, prevent his being a source of contamination. This is the sort of education that is required. It may be trusted to produce beneficent effects far and away beyond those of any number of lectures or sermons, and in the long run will secure that co-operation on the part of the entire population without which the most elaborate legislation must needs remain inoperative.

## Notes on Current Topics.

### The Jenner Society.

THE report of this Society for 1899 and 1900, somewhat tardily published, affords a very good idea of the results of the last vaccination legislation. There has been an increase in the number of vaccinations equivalent to 33·8 per cent., and the ratio of successful vaccinations has also undergone a marked increase. This latter fact suggests a doubt as to the genuineness of many vaccinations performed by private practitioners under the old *regime*, indeed, it was a matter of public notoriety that, in deference to the whims of parents, some practitioners were in the habit of complying with the letter, rather than with the spirit, of the law. The improvement may be attributed in part to restored public confidence in the protective powers of vaccination as the result of the very thorough investigation at the hands of the Royal Commission, and partly also to the fact that vaccination has been brought to the doors of the great mass of indifferent people who, while they would not take any trouble to obtain the protection for their offspring, do not directly refuse compliance with the law. On bigoted anti-vaccinators the effect has been *nil*, except, perhaps, in that it has rendered them more obstinate and irreconcilable than ever. As the report says, when a man commits himself to a position which he can neither maintain intelligently nor abandon without virtually confessing that he has blundered, he is more likely to be exasperated than conciliated by being treated with magnanimity. The report deprecates the attitude of certain well-meaning magistrates who have placed difficulties in the way of the *soi disant* conscientious objector, and urges the maxim, *surtout pas trop de zèle*. Unquestionably this magisterial attitude has done something to maintain the feeling of hostility to vaccination, and is unattended by any compensating gain to the community. The imposition of heavy fines on obstinate recalcitrants is also disadvised as enabling them to pose as martyrs. The public vaccinator, it is pointed out, is still handicapped by competition with practitioners who content themselves with a single mark, and it is urged that there should be a statutory definition of what constitutes successful vaccination, otherwise vaccination is liable to be brought into discredit by reason of the inadequate protection afforded thereby. The only other alternative is that vaccination shall be done exclusively by men not engaged in private practice. We commend this report to the notice of our readers on account of the useful information which it contains on the working of the Acts and on the advantages of this method of protection against small-pox.

### Professor Koch and His Critics.

OPINIONS are divided, even in Germany, on the question of the identity of bovine with human tuberculosis. Virchow, on the one hand admits that the two are different, and even claims to have entertained this view all along, but he points out that

the non-identity of the two diseases does not necessarily entail the non-transmissibility of cattle tuberculosis to human beings, indeed he alleges clinical evidence to the contrary. He adds certain views which candidly do not assist in the understanding of the questions at issue. He warns us, for instance, against considering everything formed in connection with the tubercle bacillus as tubercle "since there are both bacillary and non-bacillary tubercle." Moreover, his opinion is that a small number of bacilli is not injurious, and he complains that this question of quantity has not been considered by bacteriologists. Professor Klebs, on the other hand, is very hostile to the view that human and bovine tuberculosis are essentially different, and he mentions a number of cases in which both adults and children have been infected by drinking the milk of tuberculous cows. He declines to admit that Koch's views are conclusive. In the mean time the German Government has appointed a committee, of which Professors Virchow and Bollinger are members, to investigate the points in question. It is officially laid down that there is at present no ground for modifying the precautions which are taken to prevent the spread of tuberculosis by milk and butter. It may be several years before the question of the difference of human and bovine tuberculosis is finally settled. Even on veterinary grounds dairy owners must still be required to sterilise their milk by means of heat, as otherwise there would be no means of preventing the spread of tuberculosis among their cattle. Consumers also are strongly urged to continue not to use milk before it has been thoroughly boiled.

### An "Eminent" Bone-setter.

A MEDICAL contemporary has drawn attention to the description of a garden *fete* recently published in the *Staffordshire Sentinel*. The Duchess of Sutherland, so it is stated, looked in at the park where the crippled children were being entertained, and was accompanied by an "eminent bone-setter," who has attended the Duchess and a number of her friends. As might have been expected this extraordinary proceeding has roused the local medical profession into arms. It is to be presumed that the crippled children were under the care of properly trained and qualified medical men. There is, perhaps, no single branch of surgery that demands more highly specialised and experienced skill than that of orthopædics. So fully is that fact recognised by most surgeons that they will not undertake the treatment of these deformities, but hand them over to their orthopædic brethren. Tenotomy, resection and grafting of bones, aseptic surgery, tendon grafting, and a host of mechanical appliances have greatly advanced the possibilities of this branch of surgical art. It seems incredible, under such circumstances, that educated people should be found ready to trust themselves and their friends to the tender mercies of a man untrained in anatomy and surgery. The responsibility of entrusting a number of cripples to an unqualified charlatan is simply

appalling, but, if we are to believe the *London Medical Sentinel*, the Duchess of Sutherland has not feared to undertake that risk. The extraordinary state of the law that permits the open practice of bone-setting by medically unqualified persons is so familiar that it hardly invites comment.

**Medical Portraits in Lay Journals.**

THE recent manifesto by the Council of the British Medical Association against the publication of the portraits of medical men in lay newspapers has received an early and somewhat amusing commentary. The portrait of the new President, Dr. Ferguson, appeared in the *London Sun* for the 7th instant, and by this time has doubtless illumined many other journalistic pages. If it be wrong for John Jones, a small practitioner in a provincial back street, to allow an enterprising editor to reproduce his classic features in the local press, surely it would be equally an ethical offence on the part of his professional brother who happens to live in a prominent position and to be the leading practitioner in the town. It really looks as if medical ethics failed to realise the fundamental principle of justice embodied in the homely proverb—“What is sauce for the goose is sauce for the gander.” The consultant condemns as an advertiser the general practitioner whose name is published in connection with this or that medical matter in the public press; but he winks at notices of his own class in connection with hospital affairs, new cures, and a score of things in which laymen are closely interested. He seems inclined to view the publication of portraits in much the same way. Not long ago a whole page, or thereabouts, was devoted in a South Wales newspaper to the portraits of the honorary medical staff of the Cardiff Infirmary. It would be interesting to ascertain how the Council of the Association propose to deal with wholesale offences of that nature.

**The Annual Dinner of the British Medical Association.**

A CORRESPONDENT writes:—The annual dinner of the British Medical Association, held this year at Cheltenham, will always be remembered as an occasion which was characterised by a series of “dumb crambo” shows on the part of those who were set down on the official programme as the speakers for the evening. It was useless for the Chairman, Dr. Ferguson, the President of the Association, to appeal to the audience for a few minutes’ quiet. The guests, to the number of over 400, had evidently come there to enjoy each other’s society and conversation; they did not actively object to the speakers, but they certainly were not going to listen to them, and so in a perfect babel of loud and cheerful talking and of roars of laughter, together with the noise of many waiters moving about, a long toast list was worked through. A curious fact was that the inability to be heard did not in any way affect the length of the speeches. In the case of one orator every artifice was employed to convey to the speaker the fact that time was short and others were to follow, for even the

bugler from the band was commandeered and loudly sounded the “Cease fire,” but all to no purpose—the eloquent but unheard oration was not shortened by one single sentence. With the exception of the trouble about the inability to hear the official speeches the dinner went off exceptionally well, and moreover many of those present were heard to declare that it was the most enjoyable public dinner they had attended for a long time.

**Medical Guardian and Medical Officer.**

SOME time since we alluded to the complaint brought by the Medical Officer of the Newton Abbott Workhouse against one of the guardians, also a medical man, on the ground that the latter in his official visits interfered with the treatment of the patients and criticised the diagnosis. A Committee of Inquiry was appointed, and they reported that the evidence was “not sufficient to find that any intentional interference had taken place.” One might have expected that the incident would end there, but with glorious inconsistency the guardians subsequently passed a vote of confidence in their medical officer, coupled with the hope that “he would have no further cause to complain.” It really looks as though either the medical guardian or the medical officer would do well to resign, and it is to be regretted that a purely personal matter of this kind should disturb the harmony of the Board. On the whole our sympathies are with the medical officer, who is perfectly justified in resenting even the appearance of interference with his professional functions by a fellow-practitioner.

**The Causation of Phosphorus Necrosis.**

ONE of the most useful addresses delivered at the Cheltenham meeting of the British Medical Association was that by Mr. W. F. Dearden, of Manchester, on “The Causation of Phosphorus Necrosis.” According to one school the fumes of the lower oxide of phosphorus given off from the moist phosphorus paste, in the course of manufacturing matches for use on the Continent, exercise an influence that is purely local. In the opinion of another body of thinkers the maxillary necrosis is a local manifestation of a general disturbance of the system. Mr. Dearden has very skilfully worked out his reasons for partially accepting both these views. He adopts, in fact, the commercial method of “splitting the difference.” It certainly seems clear that the possession of carious teeth is a necessary factor in exciting the acute local necrosis, but it is equally certain that phosphorus fumes exert no specific action on exposed bone or periosteum. There must be some systematic predisposing influence from a primary infection of the tissues acting as a necessary adjunct to the local excitation. This explanation places the local irritation as the actual exciting cause in quite a secondary position. This contention is borne out by the comparative frequency of the occurrence of spontaneous fractures of the long bones in match-makers of many years,

standing, and the brittle condition of the bone assuredly accounts in some degree for the low resisting power of the jaw to local inflammatory injury. Further, the bone of a match-maker and healthy bone show a distinct difference in the relative proportions of phosphoric acid to lime, and this also is observed in cases of "phossy jaw." By the aid of the X-rays it can be demonstrated that bone formed in young people working at phosphorus processes during the growing period is much denser in character than it would otherwise be. We quite agree with Mr. Dearden in his conclusion that certain changes do take place in bone tissue as a result of inhaling phosphorus fumes for long periods, and that it is reasonable to account for "phossy jaw" by local irritation through a carious tooth acting on bone already damaged as the result of a general infection.

#### How Cheltenham was Saved from Small-pox.

It is so usual to connect Government offices with red tape, delay, and muddle that when the Mayor of Cheltenham recently referred to the sensible manner in which the efforts of that city to control the well-known outbreak of small-pox at Gloucester were helped and encouraged by the Local Government Board his audience of medical men greeted the announcement with loud applause. In neighbouring Gloucester there were 430 deaths from small-pox recorded, and it was felt that immediate steps ought to be taken at Cheltenham, so the Mayor and Council snapped their fingers at precedent, and on their own authority made every medical man in the place a vaccination officer, and within a week or so the vaccination and re-vaccination of over 10,000 people was carried out. Twenty-three cases of small-pox were imported from Gloucester into Cheltenham; these were duly isolated, and the Mayor had reason to be proud in recalling the fact that they had not a single death in Cheltenham from the disease. The Local Government Board not only winked at the irregularity, but put matters straight by granting certificates to the medical men as Government vaccination officers.

#### Sanitary Bedding.

A CORRESPONDENT calls attention to the curious indifference of English people to the quality and cleanliness of their bedding, at any rate of certain parts thereof, notably the mattresses. He points out that in France even the working people are not content to lie on mattresses made up of the *débris* of old woollen rags, carpets, &c. Their bedding is of white wool and horsehair, and at least once in two years the mattress is picked to pieces and carded by itinerant women. There is undoubtedly much truth in the reproach, for the practice of having mattresses re-made seems to be almost unknown in England. This may be the effect or the cause of the process being so costly as not to be accessible to persons of moderate means. The consequence is, as many of us know to our cost, much discomfort and, not improbably, injury to health, for dust and dirt must accumulate in the interstices of the mattress

and undergo decomposition. The advantage of having the process of carding carried out under one's eye, so to speak, is that there is less risk of any portion of the contents being stolen or replaced by inferior material against which one can have no guarantee when it is sent to a factory.

#### Action for Slander.

A CURIOUS action for slander against a medical man was tried at the Birmingham Summer Assizes last week, when Mr. Gray, a dentist, claimed damages from Dr. E. W. Welchman, J.P., for having declined to give chloroform for a patient of his on the ground that he (the plaintiff) was not a qualified dentist. It appears that, as a matter of fact, the plaintiff is actually on the *Dentists' Register*. The defendant in his defence pleaded that he had received a circular warning him not to assist any unqualified dentist, and though the plaintiff's name was on the *Register* it was only in virtue of his having been in practice before 1878. The Judge put it to the jury that if the defendant had acted under apprehension of consequences in the event of the dentist being unregistered their verdict ought to be in his favour, and the jury thereupon returned a verdict for the defendant, to which the Judge added costs.

#### Unremunerative Honours.

ELECTION to the post of direct representative on the General Medical Council appears to be a somewhat onerous distinction, judging from Mr. George Brown's experience. In his speech at Cheltenham he plaintively referred to the fact that his annual fifty cases of midwifery had dwindled down last year to one, and that one a *gratis* case, in consequence of the demands on his time by attendance at the Council at Committee meetings. This is certainly a serious state of affairs, for the loss can hardly be compensated by the five guineas per afternoon dole which is all that the members get. As Mr. Brown put it colloquially, the post is "not a very fat thing." In spite of this disastrous effect on his practice, Mr. Brown asserts his willingness to continue his self-sacrificing efforts on behalf of his professional brethren. It remains to be seen at the next election whether his brethren will consider themselves justified in imposing the sacrifice upon him.

#### Diachylon.

THE frequent use of diachylon as an abortifacient in the city of Nottingham led to the Nottingham Medico-Chirurgical Society calling the attention of the British Medical Association to the matter. The matter was passed on to the Pharmaceutical Society with the request that steps should be taken to have diachylon scheduled as a poison. The Pharmaceutical Society appointed a special committee of the Council to consider the desirability of extending the schedule to the Pharmacy Act, 1868, and the correspondence from the Nottingham Medico-Chirurgical Society has been remitted to the special committee referred to. The members of the medical profession at Nottingham are to be complimented on the very

judicious course they have pursued in this somewhat difficult condition of affairs.

#### Reform in Soldiers' Dress.

THE dress of the soldier is one of the points that demands firm handling in the new era that it is not altogether unreasonable to hope will ere long descend upon the British War Office. At present the full dress uniform of many privates and of most officers is a survival of monumental foolishness, unfitted for either the arts of war or the purposes of peace. The garments are so heavy and tight fitting that they permit no departure from the constrained stiffness of the warrior standing at "attention," to say nothing of the fact that they are coloured so gaily, and loaded so heavily with metal buttons, and lace and other finery as to be a constant source of wearing anxiety to their owners. The first thing an officer does on returning from a full dress parade or other function is to revert to his loose patrol jacket. Indeed, it is rumoured that if Mr. Brodrick's proposal that officers in future should wear their uniform in public were carried out, at least half of the present army officers would forthwith resign. Why, then, should these uniform absurdities, which are so heartily disliked in the army itself, be retained to delight the hearts of servant-maids and drill-sergeants, not to mention army tailors? A good beginning has been made in the matter of supplying many regiments with slouch hats. In Italy the whole of a regiment while manœuvring near Naples recently, was attacked by malaria. The Minister of War has since issued orders that all troops in that district are in future to wear veils and gloves to protect them from mosquitoes. The good sense of that proceeding may well be commended to our army authorities at home. The relation of dress to disease is a most important point in military administration, and one worthy of the highest skilled investigation and control.

#### Underground Bakehouse Legislation.

THE question of underground bakehouses has again come prominently before the public by reason of certain amendments proposed in the Factory Acts, which will probably have been settled in the Commons one way or the other within a day or two. The main proposition brought forward is that all underground or cellar bakeries shall in future be abolished, except in cases where the local sanitary authority grant a special certificate of the fitness of the premises from a health point of view. In practice any condition of the kind is likely to reduce legislation to a dead letter. Experience has shown that many bakers are actually members of vestries or councils, and oppose any action against their fellow-tradesmen tooth and nail. There is also often a strong undercurrent of opposition on such boards against any interference with trade interests. The reasons why underground bakehouses should be abolished are numerous and weighty. They affect the health not only of the producers but also of the consumers of bread. The whole case has been investigated by

Drs. Waldo and Walsh, who have published a book, "Bread, Bakehouses, and Bacteria," which has for some years been the authority upon this subject, and has formed the basis of all recent bakehouse legislation. Their chief scientific point was the demonstration of the fact that the ordinary loaf is not sterilised by baking. If non-pathogenic microbes survive the ordeal of the oven it is fair to assume that pathogenic micro-organisms will also retain their vitality under similar circumstances. This non-sterilisation of the dough in baking proves the absolute necessity of a perfect sanitary environment in the bakehouse.

#### The Folly of Bolting Food.

A PAPER read before the British Medical Association furnishes some remarkable facts about the mastication of food. The author, an English practitioner in Venice, says that there exists a lost reflex action of the throat, whereby it refuses to swallow food unless well chewed and mixed with saliva. After five or six weeks of prolonged and careful chewing of solids and prolonged insalivation of fluids, this reflex can be restored. The necessary condition of success is that both fluids and solids shall be dealt with in the mouth until they are reduced to a tasteless condition. The author says that by adopting his process indigestion is vanquished, the body becomes healthy, a far smaller quantity of food is required, and in one case corpulency was reduced to an extraordinary extent. If his views be accepted the treatment of many maladies will be simply revolutionised. With the modern man quick eating has become a necessity, at any rate in the breakfast and luncheon hours. The tendency is to bolt everything at those meals, and to eat far too quickly even when there is ample time at disposal. It is clear that prolonged mastication would render a dinner of many dishes impossible. It is equally clear that most of us eat far more than is needful to satisfy our bodily requirements. That there is something to be said on the side of the quick eaters, however, may be gathered from the fact that many of them pass long lives without being overtaken by the Nemesis of dyspepsia. Among many native tribes, moreover, and with a host of carnivorous animals, it is the rule to bolt food in rapid and wholesale fashion.

#### The Public Endowment of Cancer Research.

THE shadows of the scientific world have long hinted at coming events in the curative and preventive aspects of cancer. It is now pretty generally believed that the dread disease in question is due to a parasitic organism which has gained access to the human body. If that be the case cancer is at once brought within the category of infectious and therefore preventible maladies. The importance of accurate knowledge upon these points to mankind generally can hardly be over-estimated. One is not surprised, therefore, to find an intelligent layman writing to the newspapers and advocating a plan whereby a number of endowments of £500 per annum

may be established for the benefit of medical men who will undertake special investigation of the disease. While fully endorsing the value of this suggestion we can hardly agree with his proposed plan of selecting the workers from physicians and surgeons with a large experience of the disease, and requiring them to work in the cancer wards of a general hospital. The purely clinical aspects of the disease have long been worked out, and the crucial problems of causation must be solved in the pathological and bacteriological laboratory. By all means let us have liberal endowments for cancer research, but let the money be spent in the right direction. Any philanthropist wishing to confer a lasting benefit upon the human species could hardly do better than found a special cancer laboratory. That would in many cases be a more logical and strictly philanthropic proceeding than the creation of pseudo-medical charities.

#### Indiarubber Corsets.

THE corset, as all the world knows, is an essential detail of the costume of the modern civilised woman. We use the term "modern" advisedly, because early woman was free from that artificial aid to symmetry which has appeared upon the scene only within the last hundred years or so. That it has some quality which commands the admiration of the fair sex is clear as daylight, otherwise it would have gone the way of crinoline and high waist and a hundred and one other absurdities of dress. The principle of the corset is that it supplies a "figure" built upon the unbending lines of beauty laid down by the dressmaking craft as the beau ideal of the feminine form divine. To that end this article of dress is made practically as a cuirass of stiff material strengthened and strutted with slips of steel, whalebone, and wood. The apparatus, in its present stage of evolution, has gained the wholesale contempt and detestation of all physiologists as an outrage upon the organs of respiration, circulation, and digestion. Lovely woman, however, contemptuous of mere scientific criticism, has carried her fashion a step nearer breaking-point by inventing corsets of indiarubber designed for bathing purposes. The idea of thus converting what should be a most wholesome and health-giving recreation into a field for exploiting various kinds of irrational dress could have been engendered only in the brain of a latter-day fashionable woman.

#### The Army Medical Service Committee.

SIR WILLIAM THOMSON, C.B., Fellow and late President of the Royal College of Surgeons in Ireland, has, we understand, been offered a seat on the Committee appointed to inquire into the present state of the Army Medical Department. Even if Sir William Thomson is able to accept the invitation, the representation of Irish Schools on the Committee will still be altogether too small, when it is taken into consideration that the number of medical officers in the B.A.M.C. who hold Irish qualifications

at present is equal to 37 per cent. of the entire number of officers. Sir Thornley Stoker, F.R.C.S., Ireland, has addressed a second letter to *The Times*, in which he calls attention to the fact that there is still insufficient representation.

#### Wage Limit.

THE question of the wage limit is generally believed to be a subject in which practitioners are keenly interested. It would, however, seem open to question whether, after all, the medical profession is really interested in this matter. In any event, it is noteworthy that although all the branches of the British Medical Association were written to, asking for the opinion of their members on the wage limit question only nine branches replied, and the others are now being stirred to activity by urgent appeals from the central authority to "give this important matter their careful and early attention." This fact certainly argues in favour of the opinion that this so-called burning question is in reality regarded with something akin to indifference by medical men in this country.

#### Cigarette Smoking.

Two hundred medical practitioners in Edinburgh and Leith have signed a memorial against cigarette smoking by children, and urging that steps should be taken by Parliament to restrict the sale of tobacco in any form to lads under sixteen years of age. There is no difference of opinion in the profession as to the deleterious effects of cigarette smoking by the young, but we are fain to admit that legislative prohibition will be very difficult to obtain and still more difficult to enforce.

#### A Warehouseman Vaccinator.

A GLASGOW warehouseman has recovered three guineas and expenses from the Glasgow Corporation for vaccination fees. It transpired that the plaintiff had been employed by the Corporation to vaccinate during the recent epidemic, and was promised six shillings a day, i.e., the same rate as that paid to medical students. The Glasgow corporation is known to be very enterprising, but this is an innovation of which it is difficult to approve.

AN action was tried last week at the Glamorgan Assizes in which a miner claimed damages from Dr. Ward, of Merthyr, for alleged negligent treatment. The plaintiff had sustained a fracture of the left forearm, and a false joint had resulted. Mr. Robert Jones, of Liverpool, was called on behalf of Dr. Ward, whose defence was looked after by the Medical Defence Union, and distinctly negated any suggestion of malpraxis, and a verdict was returned in favour of the defendant.

THE death is announced of Dr. Julius St. Thomas Clarke, of Leicester, which took place quite suddenly on the 2nd inst. Dr. Clarke, we may recall, was the victim of an assault by a lunatic last October, when he was shot with a pistol, the ball lodging in the lower part of the spine. There is no reason, how-

ever to think that his death had any direct connection with the injury.

PERSONAL.

MR. W. WATSON GRIFFIN, M.B., F.R.C.S., has been appointed Ophthalmic Surgeon to the Sussex County Hospital.

SUBRON-GENERAL T. F. O'DWYER, P.M.O., will shortly retire from the service on completion of his tenure of his appointment at Aldershot.

DR. C. W. DANIELS left Liverpool on the 8th inst., by the ss. "Sekondi," for Sierra Leone, West Africa, to join the sixth malarial expedition under Major Donald Ross.

THE resignations of Dr. Bassett Jones and Dr. Morgan, Honorary Surgeons of the Aberystwith Infirmary, have been accepted at a meeting of the management committee of the institution.

SIR FRANCIS R. CRUISE, M.D., Fellow and ex-President of the Royal College of Physicians of Ireland, has been appointed one of the honorary physicians to His Majesty the King in Ireland.

DR. FARQUHARSON, of Lichfield, has been appointed Medical Officer of Health to the Bishop Auckland Rural District Council, at a salary of £350 per annum. There were forty-two applicants, and the advertisement stipulated for whole services to be devoted to duties of the office.

A PORTRAIT of Dr. Thomas Young, copied from the painting by Sir Thomas Lawrence, has just been placed in the Victoria Hall, Milverton, Somerset, with an inscription in which he is described as "physician, natural philosopher, and master of many languages." Dr. Young died in 1775.

DR. HENRY C. WOODS, C.V.O., one of the King's Naval Honorary Physicians, who served in the Royal yacht "Victoria and Albert" from February, 1887, until his retirement a few months ago, has been appointed to a special post at the Admiralty, and has commenced his duties in Northumberland Avenue. Dr. Arthur R. Bankart, M.V.O., who attended the Khedive in the "Osborne" in July last year, has been appointed to Dr. Wood's vacant post in the Royal yacht.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

BRITISH AND COLONIAL JOURNAL OF OBSTETRICS AND GYNÆCOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your editorial note appended to the letters which appear in THE MEDICAL PRESS AND CIRCULAR of July 31st you state the opinion that "there is room for an 'imperial' journal of obstetrics and gynæcology." I can confidently assure you that it is an "imperial" journal which the promoters aim at, and they will be satisfied with nothing less.

There appears to be some misapprehension in certain quarters as to the origin of the present movement, and

the aims and motives which have influenced its promoters and supporters. It is difficult to see how any misunderstanding could arise. There never has been any attempt to conceal the incidents in the movement, and there can be no possible objection to a frank statement of what has occurred.

After conversations and consultations extending over many months among certain members of the North of England Obstetrical and Gynæcological Society, an informal provisional committee was formed at the beginning of this year with the object of ascertaining the views of the specialists of the United Kingdom and of the Empire at large on the feasibility of establishing a journal of obstetrics and gynæcology worthy of being ranked with those of Europe and America. This committee was selected according to definite principles in order to obviate any misunderstandings among the members of the Society, where so many were well fitted to undertake the work in hand. It consisted, when complete, of all the official teachers of midwifery and diseases of women in the four medical schools of the provinces covered by the Society. It was felt that we must first find out if the gynæcologists were strong enough to found a journal, and no appeal must be made in the first stage of the enterprise to the hospital surgeons who to some extent specialise, whether or not they were members of the various obstetrical or gynæcological societies.

I undertook the chief part of the correspondence, and was assisted by my junior colleagues, Drs. Arnold Lea, W. E. Fothergill, and Arthur Wallace.

We were all firmly convinced that the time had come for a successful enterprise of the kind, but we harboured no illusions. We knew it was a venture; we did not feel justified in formulating a scheme; we could not, therefore, influence opinion; we could only try to ascertain it and report. Most of our correspondents were as well acquainted with the position of British gynæcology as we were ourselves.

Out of the extensive correspondence which is now in my possession two facts soon became prominent: first, that the gynæcologists of provincial England, Scotland, and Ireland were practically unanimous and cordially favourable to the scheme, while the teachers of obstetrics and gynæcology of the Colonies and dependencies of the Empire were absolutely unanimous, and if possible more cordial still in their expressions of interest and promises of support—Canada, Australasia, India, without a Laodicean. Secondly, that the difficulties arising from apathy or hostility among certain circles of London gynæcologists were well nigh insuperable. To our surprise many of the friends and opponents of the scheme appeared in entirely unexpected quarters. There was not the clear line of cleavage which we anticipated from a more or less intimate acquaintance with the contemporary history of gynæcology in London.

To those of us in the north who know the motives and aspirations of the original promoters of the scheme it is startling to read that "it is an open secret the journal has been conceived and taken in hand mainly by those who are openly and avowedly hostile to the British Gynæcological Society and its *Journal*." No statement could more completely misrepresent the facts. It would be nearer the truth to say that the main obstacle in the way of smooth and rapid progress with the arrangements has been the hostility of the most influential members of the British Gynæcological Society residing in London. Yet there are many exceptions; verbally and by letter, both directly and indirectly, the provisional committee has received assurances of friendly interest, which will doubtless be changed to active support in due time.

The objections on the part of the leading men are natural and obvious enough; they are highly creditable to their loyalty, if not, with all respect, to their discrimination of the signs of the times and the requirements of contemporary British gynæcology. One of the most respected and influential members writes:—"I have spoken to several of our men and am confident that they will take no action without fully understanding how the Gynæcological Society is likely to be affected by the movement." And yet many of the

most active supporters of the new journal scheme are provincial or Colonial members of the British Gynaecological Society, and do not believe that they are acting in a way to prejudice its prospects. In my humble opinion the Society will be in the same position as other similar societies throughout the country which periodically print and distribute to the members the papers and contributions brought forward at the meetings, and its quarterly journal will not lose in the slightest its value, even if many of the contributors to its admirable abstracts and reviews of the contemporary literature of obstetrics and gynaecology could find energy and inclination to take part in similar work on the new journal. Why should such participation be considered incompatible with entire loyalty to the British Gynaecological Society? Let me also add that all the objectors and a good many apathetic correspondents appear to under-estimate entirely the character and position which the promoters intend the new journal to assume. Even with moderate success it must belong to a different category from anything at present published in this country. It will be necessary to look to Germany for something to compare with it in scope and quality. No question of rivalry can arise here. The only emulation should be in a patriotic endeavour to concentrate the intellectual activity of the Empire in a certain field of professional work so as to produce the highest possible result.

Our local provisional committee, after consideration of the correspondence, came without hesitation to the conclusion that we must proceed with the undertaking. The response surprised while it gratified the most sanguine among us. We deplored the sporadic apathy or hostility in London, but there could now be no question of the experiment being made.

The most natural proceeding appeared now to be the calling of a meeting of the friends of the scheme to take counsel as to the next steps. In arranging for such a meeting in co-operation with the most cordial and influential supporters of the scheme among the London colleagues, it was surely natural to invite the attendance of those who had from the first been unequivocally friendly to the enterprise? The promoters could at least count on friendly criticism and advice intended to be helpful. Whether the meeting would consider the moment opportune was another matter. In the name of practical common sense, what useful purpose could have been served by the introduction of a known hostile element even though small in amount numerically? Objections such as would emanate from a friendly source had been all well considered.

The circular calling the meeting was signed by twenty-four representatives of British gynaecology, and it was sent to between 180 and 140 medical men and women known chiefly as practising obstetrics and gynaecology in the United Kingdom. The list was compiled from reports supplied by the most prominent specialists in the various centres of population. The meeting was attended by representatives from every part of the country, and from the point of view of the promoters was most successful and satisfactory. A resolution was passed unanimously to the effect that it is desirable to establish a journal of midwifery and diseases of women for the British Empire, and that the time is opportune for the undertaking. A committee was then appointed to give effect to this resolution. That committee is now at work; it has reported to an adjourned meeting, and it will soon be able to announce the results of its deliberations.

In your note referred to you ask, "Who is responsible for the assumed privacy?" The privacy, Sir, is altogether assumption. It is a figment of your correspondent, and implies considerable creative power. "Privacy" of meetings twice summoned by seven score printed circulars, in association with unlimited correspondence and the most unconstrained conversation and gossip! There has been, of course, the usual conventional official reticence on the part of those chiefly responsible for the summoning of the meeting. It would have served no useful purpose to have laid themselves prematurely open to worry and misrepresentation from anonymous writers in the medical journals. What would the

objectors have done under the circumstances? If they had been conscious of the support of practically the whole British Empire, would they, knowing the unhappy differences among London gynaecologists, have begun the movement by proclaiming its initial stages from the hearthstone, or have called the meeting by advertisement? Or could they have postponed action towards the fulfilment of the wishes of the vast majority of their colleagues throughout the Empire until London factions were reconciled?

The committee which is making arrangements for bringing out the journal is, perhaps, just as representative as any that could be formed so as to include the same proportion of men who are practising purely as specialists in the United Kingdom. The names will appear in a circular which is in course of preparation and will be issued shortly. The list of collaborators who will be invited to co-operate with the editorial staff, and will include the names of the best known workers both at home and in the distant parts of the Empire, will also be published in due course, but its compilation is a work that requires time. In what they do the committee will be guided, I believe, only by the desire to make the future journal successful in every way. Whether the members reside in London or in any other part of the kingdom they are influenced as much by a patriotic desire to see one of the reproaches removed from British medical science, and as little by jealousy of individuals or of institutions, as are the men who write cordial letters in support of the journal scheme, with friendly wishes and helpful suggestions, from Montreal and Toronto, from Melbourne and Sydney, or from Calcutta and Madras.

It would be to me a cause for deep regret if by want of clearness in expression I should appear to say anything to hurt any susceptibilities. That is far from my intention. There is surely room for all patriotic men scientifically interested in their professional work to join in this enterprise? A British Empire journal will certainly be published, and it is my firm conviction that it will be established. It will be representative of British gynaecology in the fullest sense, and it will hold up its head in the presence of the best that Germany or France, or Italy or the United States of America can produce. Assuming the role of prophet like your correspondents, who prophesy failure, I can confidently predict that it will not be so very long before some of your correspondents, looking back on their efforts at opposition, will be congratulating themselves that they wrote anonymously.

I am, Sir, yours truly,  
W. J. SINCLAIR.

#### Birmingham Libel Case.

A SETTLEMENT was announced at the Birmingham Assizes, on the 6th inst., in the action brought by Dr. Alfred Hill, the Medical Officer of Health for Birmingham, against the *Birmingham Daily Gazette*. The ground of the action was that the *Gazette* had imputed to the plaintiff responsibility for shortcomings in the housing of the poorer classes. Defendants consented to judgment for £250 and costs, and withdrew the reflections complained of, but claimed to have acted *bona fide*.

#### Another Beer Poisoning Sensation.

A GREAT sensation (says the *Newcastle Journal*) has been caused in Trowbridge and district by the publication of the annual report of Dr. Thomas, County Medical Officer of Health for Wiltshire, in which it is stated that last December arsenic was found in beer from a certain brewery, and that in consequence a number of persons suffered from arsenical poisoning through drinking such beer. The attention of the brewer was called to the matter, and a sample of the glucose used was given to Dr. Thomas, which also was found to contain arsenic. The brewer immediately withdrew the contaminated beer from sale, and undertook to destroy the beer in stock. Samples of beer and glucose afterwards obtained and analysed were found to be free from arsenic.

#### The Dental Hospital of London.

HIS MAJESTY THE KING has been graciously pleased to grant his patronage to the Dental Hospital of London

which has recently been rebuilt in Leicester Square, London.

**Vital Statistics.**

THE deaths registered in the week ending August 3rd in 86 large towns of Great Britain and Ireland corresponded to an annual rate of 22.4 per 1,000 of their aggregate population, which is estimated at 11,463,026 persons in the middle of this year:—

Birkenhead 24, Birmingham 25, Blackburn 22, Bolton 24, Bradford 18, Brighton 17, Bristol 13, Burnley 25, Cardiff 11, Croydon 9, Derby 21, Dublin 20, Edinburgh 17, Glasgow 21, Gateshead 33, Halifax 11, Huddersfield 18, Hull 19, Leeds 29, Leicester 21, Liverpool 30, London 20, Manchester 29, Newcastle-on-Tyne 31, Norwich 15, Nottingham 23, Oldham 18, Plymouth 14, Portsmouth 29, Preston 27, Salford 25, Sheffield 23, Sunderland 27, Swansea 14, West Ham 31, Wolverhampton 11. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 2 in Edinburgh, 7 in Glasgow, 1.4 in Birmingham and in Sheffield, and 2.1 in West Ham and in Salford; from scarlet fever, 1 in Edinburgh, 1 in Glasgow, 1.2 in Blackburn, and 1.8 in Preston; and from diarrheal diseases, 27 in Dublin, 12 in Edinburgh, 73 in Glasgow, 5.1 in Newcastle-on-Tyne, 5.3 in Sunderland, 5.4 in Hull, 5.5 in Huddersfield, 5.9 in Leicester, 7.6 in Birmingham, 8 in Birkenhead, 8.6 in Burnley, 9.4 in Gateshead, 9.5 in Nottingham, 9.9 in Bolton, 10.1 in Leeds, 10.6 in Salford, 11.6 in Manchester, 11.8 in Portsmouth, 12.4 in Sheffield, 12.8 in Liverpool, 13.8 in Preston, and 14 in West Ham. In none of the large towns did the death-rate from whooping-cough, or from "fever" reach 1.0 per 1,000. The 69 deaths from diphtheria included 28 in London, 6 in Leeds, 5 in Sheffield, 5 in Leicester, 3 in Brighton, 3 in Cardiff, 3 in Manchester, and 3 in Salford. One death from small-pox was registered in London, but not one in any other part of the United Kingdom.

**Death under Ether at Leeds.**

AN inquest was held at Leeds a few days since on the body of H. Hodgson, æt. 12, of Piley Hill, Dodsworth, who died while undergoing an operation at the Leeds Infirmary, for a nasal obstruction. It was stated that the proper quantity of ether was administered, and after the operation had commenced the boy went into convulsions, which lasted about twenty minutes. Restoratives were applied, but in vain. The jury returned the usual verdict.

**The Sale of Drugs by Medical Graduates.**

THE Senate of the University of Aberdeen has issued the following pronouncement:—"Whilst it is admitted that the exigencies of practice in certain localities may sometimes render it unavoidable for a medical practitioner to supply to his patients the remedies which he prescribes, the Medical Faculty of this University is of opinion that it is undesirable and detrimental to the position of medical graduates of the University that this custom should be followed under other circumstances; and further, it regards the sale of objects other than remedies by its medical graduates as, under all circumstances, to be strongly deprecated."

**Dublin Death-rate.**

DURING the thirty-one weeks ending with Saturday last the death rate of Dublin averaged 27.9 a 1,000. The rate of mortality in London was 20; Edinburgh, 17.3; Paris, 18.4; New York, 19 per 1,000. Fifty-eight of the persons whose deaths were registered during the week were under five years of age (45 being infants under one year of age, of whom eight were under one month old). There were 23 deaths from diarrhoea, four from simple cholera, and four from whooping-cough.

**The Mortality of Foreign Cities.**

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 114, Bombay 47, Madras 38, Paris 17, Brussels 14, Amsterdam 13, Rotterdam —, The Hague —, Copenhagen 21, Stockholm 15, Christiania 22, St. Petersburg 25, Moscow 36, Berlin —, Hamburg 20, Dresden —, Breslau 38, Munich 19, Vienna 17, Prague 23, Buda-Pesth 18, Trieste 23, Rome 17, Turin (10 days) —, Venice 23, Cairo 45, Alexandria 37, New York (including Brooklyn) 19, Philadelphia 26.

Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on July 27th with the following results:—

**First Examination.**—Of thirty candidates entered, the following fourteen passed the examination:—Leopold H. Gill, George A. S. Hamilton, James Murphy, Jessie Jean M. Morton, Henry G. Smith, James Watson, Ayodeji Oyejola, Edith Boomgardt, Ernest P. Titterton, George H. Waugh, Robert M. Fraser, Nicholas D. Sweetnam, William P. Walker, and Charles S. P. McDermott; and five passed in physics, four passed in elementary biology, and one in chemistry.

**Second Examination.**—Of twenty-seven candidates entered, the following fourteen passed the examination:—Joseph van Someren Taylor (with distinction) William H. Bealch, Broderick E. M. Newland (with distinction), Richard H. Rigby, Debendranath Banerji, Sybil Louie Lewis, John J. Lawton, Stephen McCarty, Bessie Chapple, Eileen FitzGerald, Claude E. Watts, Patrick Shaw, Robert D. Hirsch and William E. O'Hara; and two passed in anatomy and one in physiology.

**Second Examination.**—Of eight candidates, entered the following six passed the examination:—Andrew P. Walker, William F. Waugh, Urban Burston, Fergus D. Yourelle, John C. Grant and John Martin.

**Third Examination.**—Of twenty-six candidates entered, the following sixteen passed the examination:—Adam W. Hall, Thomas A. Mendes, Leo Levi, Charles S. Macaskie, John A. Douglas, William P. Cowper, Thomas J. Walsh, William J. Gray, John M. Gerety, George J. Harman, Annjuta Kellgren-Cyriax, Alice Esther Gilford, Peter O. Jollie, Shavaksha P. Mistri, Henry Carlaw, and John O'Connor, and one passed in anatomy and one in materia medica.

**Final Examination.**—Of eighty-four candidates entered, the following forty-eight passed the examination and were admitted L.R.C.P.E., L.R.C.S.E. and L.F.P., and S.G.:—David Mitchell, James C. Nicholson, Alfred A. Beeks, Claude St. Aubyn-Farrer, Jas. A. Baird, Frank J. Pattee, Raoul F. de Boissiere, Neil Gavin, Alice M. Marval, John B. Mason, Alice D. Sibree, Alexander W. Frew, Bernard Wood, Anthony Corley, Harry Holden, Norman L. Stevenson, Joseph Crawford, Frederic W. McCay, David G. Metheny, David L. Williams (with honours), Charles W. Sharp, Gopal Chunder Ghose, Michael B. Conroy, Alice E. Brown, Jeanie Newton, Walter G. Edwards, Herbert E. J. Batty, Cecil E. Martin, Augustus D'Souza, Jaysing P. Modi, Thomas F. Okell, Henry E. Blackwood, Patrick W. McHugh, Gerald S. Coghlan, Richard Fox, Behramji B. Paymaster, Jose S. da Piedade Rodrigues, Kaikhusroo D. Cooper, Ebenezer Millicans, Donald McNeill Ford, Walter Sykes, James H. Stewart, Hirie N. Anlesaria, Herbert D. Pitt, Darabshaw F. Sanjana, William P. Grellet, Helen M. Serjeant, and John Dunlop, and six passed in medicine and therapeutics, five in midwifery, and six in medical jurisprudence.

At the July sittings of the Scottish Conjoint Board held in Glasgow the following candidates passed the respective examinations:—

**First Examination.**—William Noble Walker, James Taylor (with distinction), James Alfred Ashurst, John Macnamara, Alfred Edwin M'Dougal, Robert Johnston Crawford, Charles Conway Fitzgerald, William John Cogan, W. N. Alexander, Daniel Thomas H. Crowley.

**Second Examination, Four Years' Course.**—Thomas Marshall Metcalfe.

**Second Examination, Five Years' Course.**—William Miller Ramsay, David Haig, James Booth Patterson, Thomas M'Master Glen, Alexander Glen, William Arthur Magill, James Macarthur, Patrick Thomas Doorly, Cecil James Todd.

**Third Examination.**—Angus M'Innes, Thomas Longmore Ashforth, Alexander Russell Young, Robert Calder Blyth, David Roberts Williams, Thomas Weir M'Cubbin, David Christie, E. Vithal Khedkar, Alfred Edward Griffith, Michael David Ahern, Grace Eleanor Soltau and Constance Muriel Scott, Samuel James Mathewson, Frederick Herbert Maberly, Arthur G. Jackson.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

**READING CASES.**—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of **THE MEDICAL PRESS** and **CIRCULAR**, may now be had at the office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

### THE CHELTENHAM WATERS.

A **DISTINGUISHED** visitor, on his arrival in the town at the opening of the Association meeting, was driving from the railway station on an omnibus, and he said to the driver, "What have you got here in this town?" to which the bus driver replied, "Mineral waters." The visitor further inquired what they were good for, and the reply was "For the doctors." It was a little difficult to make the driver understand that this last remark required explanation, but when he had at last grasped the visitor's need of enlightenment on what appeared to him such a simple matter the bus driver said, "Why, the doctors prescribe the waters to their patients and it gives them rheumatism and gout."

**TUBERCLE.**—The treatment is not one to be recommended in the absence of trustworthy data concerning the *modus operandi*. Judging from the information at our disposal it would appear not devoid of danger to the patient.

**V. M.**—Yes, in our Educational Number, which will appear early in September.

**CLEOPHAS.**—Your letter will appear in our next issue.

### WHY NOT SETTLE THE QUESTION AT ONCE?

At the last meeting of the Penge Urban District Council, Mr. Councillor West asked that the medical officer of health should be instructed to give a full report on the question of the inter-communicability or otherwise of bovine tuberculosis "so that the matter should be settled once and for all." It says something for the intelligence of the Board that the suggestion was received with loud laughter. In the meanwhile it was decided to affix notices forbidding spitting in the tramway cars, which is possibly a step of greater importance than that of reporting on the communicability of bovine tuberculosis.

"Well, madam," said the doctor, "how is our patient this morning?" His mind seems to be perfectly clear this morning, doctor," replied the tired watcher. "He refuses to touch any of the medicines"—*Chemist and Druggist*.

**CARDIAC.**—We are unable to accede to your request at the present stage, though your assistance may be appreciated later.

**S. V. R.**—You will find the matter has been dealt with in our issue for May 8th of this year.

## Appointments.

- BUTLER, WILLIAM, M.B.Glasg., C.M., D.P.H., R.C.P.S.Lond.,** Medical Superintendent, Isolation Hospital, Willesden, vice D. S. Skinner, M.D., resigned, and Assistant Medical Officer of Health to the Willesden Urban District Council.
- GOUGH J. H., F.R.C.S.Edin., L.R.C.P.Lond.,** Certifying Surgeon under the Factory Acts for the Torquay District of Devonshire.
- HASWELL, W. C., M.B., B.S.Durh.,** Certifying Surgeon under the Factory Acts for the Flaxton Rural District of the North Riding of York.
- MACNAIR, NORMAN, B.S., M.D.Glasg., M.R.C.S.Eng., L.R.C.P.Lond.,** Extra Dispensing Physician to the Glasgow Royal Infirmary.
- MURPHY, DENIS, L.R.C.S.Edin., L.R.C.P.Edin., L.P.P.Glasg.,** Pathologist to the Cork North Charitable Infirmary and County Hospital.
- PATRICK, E. M.D.Durh., M.R.C.S., L.R.C.P.Edin.,** Certifying Surgeon under the Factory Acts for the South-east Bolton District.
- PEARSON, H. CARDEN, M.B., F.R.C.S.Edin.,** Surgeon to the Darlington Hospital.
- TURNER, B. R., M.B., B.S.Camb.,** Certifying Surgeon under the Factory Acts for the Oundle District of Northants.

## Vacancies.

- Birmingham City Asylum.**—Senior Assistant Medical Officer, also Junior. Salaries respectively £180 and £130 per annum, with board, apartments, and washing.
- Brecon Infirmary.**—Resident House Surgeon, unmarried, Salary £100 per annum, with furnished apartments, board, and attendance.
- County Mayo Infirmary.**—House Surgeon and Compounder. Salary

- £100 per annum, with apartments, attendance, washing, fire, and light. Application at once to Dr. M. O'Malley Knott, Castlebar. (See Advt.)
- Denbighshire Infirmary, Denbigh.**—House Surgeon. Salary £100, with board, residence, and washing.
- Devon County Asylum, Exminster.**—Third Assistant Medical Officer. Salary commencing at £125 per annum, and increasing at the rate of £10 per annum to £135, with board, residence, &c.
- Devonshire Hospital, Burton, Derbyshire.**—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.
- Eastern Counties' Asylum for Idiots, Imbeciles, and the Feeble Minded.**—Resident Medical Attendant, unmarried. Salary £100 per annum, with furnished apartments, board, and washing.
- East Riding of Yorkshire.**—County Medical Officer of Health. Salary at the rate of £400 per annum, rising by increases of £25 to £500 with allowances. Applications on or before September 28th to Clerk of the County Council, County Hall, Beverley. (See Advt.)
- Fulham Infirmary, St. Dunstan's Road, Hammersmith, W.**—Locum Tenent for four weeks. £3 3s. per week, with board, apartments, attendance, and washing.
- Kent and Canterbury Hospital.**—Assistant House Surgeon, unmarried. Salary £60 per annum with board and lodging.
- Lewes Dispensary and Infirmary and Victoria Hospital.**—Resident Medical Officer. Salary £100 per annum, with apartments, board, and attendance.
- North London Hospital for Consumption, Hampstead.**—Junior Resident Medical Officer for six months. Honorarium at rate of £60 per annum.
- Nottingham General Dispensary.**—Assistant Resident Surgeon, unmarried. Salary £180 per annum, increasing £10 every year, with furnished apartments, attendance, light, and fuel.
- Owens College, Manchester.**—Junior Demonstrator in Physiology. Salary £100 rising to £150 per annum.
- Plymouth Borough Asylum.**—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with apartments, board, and washing.
- Royal South Hants and Southampton Hospital.**—Junior House Surgeon for six months. Salary at rate of £50 per annum, with rooms, board, and washing. Also Dispenser. Salary £60 per annum, with board, rooms and washing.
- Royal Surrey County Hospital, Guildford.**—Assistant House Surgeon.—Salary £75, with board residence, and laundry.
- Staffordshire County Asylum, Stafford.**—Junior Assistant Medical Officer, unmarried, Salary £150 per annum, with board, lodging, attendance, and washing.
- Stamford, Rutland, and General Infirmary.**—House Surgeon. Salary £100 per annum, with board, lodging, and washing.
- Toxteth Park Workhouse and Infirmary, Liverpool.**—Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments.
- West Africa.**—Three Medical Officers to accompany Railway Survey Parties. Salaries £40 per month, plus allowances.
- West Ham Hospital, Stratford, E.**—Junior House Surgeon, Salary £75 per annum, with board, residence, &c.
- Wolverhampton and Staffordshire General Hospital.**—Assistant House Surgeon. Honorarium at the rate of £75 per annum will be given. Board, lodging, and washing provided. Also Assistant House Physician. Honorarium at the rate of £75 per annum will be given. Board, lodging, and washing provided.
- Wolverhampton Eye Infirmary.**—House Surgeon. Terms, £70 per annum, rooms, board, and washing.

## Births.

- GEDDES.**—On August 5th, at Winterton, Ferryhill, co. Durham, the wife of J. W. Geddes, M.B., C.M., of a daughter.
- PROBY-WILLIAMS.**—On August 5th, at 13, Welbeck Street, W., the wife of E. J. Proby-Williams, M.D., of a daughter.
- BUR.**—On August 1st, at 30, St. Mary's Road, Higher Crumpeall, Manchester, the wife of John Aust, M.R.C.S., L.R.C.P., of a son.
- SWALLOW.**—On August 2nd, at Taunton House, Clapham Road, S.W., the wife of Allan J. Swallow, M.B., B.S., of a daughter.
- WHITE.**—On July 28th, at Vanbrugh Park, Blackheath, the wife of Finch White, M.R.C.S., L.R.C.P.Lond., of a son.

## Marriages.

- CALVERLEY-DOVEY.**—On July 27th, at St. John's, S.E., Ernest Joseph Goodfellow Calverley, M.B., B.S.Lond., M.R.C.S., L.R.C.P., of Claremont House, Folkestone, to Evelyn, daughter of E. Douët, Esq., of St. John's.
- DARBYSHIRE-WORLEY.**—On August 1st, at St. John's Church, Perth, W.A., Douglas Edward Darbyshire, M.B., L.R.C.P., M.R.C.S., to Florence, second daughter of William Charles Worley, L.R.C.P., M.R.C.S., of Green Lanes, N.
- DONALD-BENNER.**—On August 6th, at St. Paul's, Winton-on-Tyne, David Donald, L.R.C.P., L.R.C.S.Edin., L.F.P. & S.Glasgow, to Bessie, daughter of the late Francis T. Benner, Newbiggin, Northumberland.
- HAY-MASON.**—On August 8th, at St. Andrew's Church, Deal, William Leslie Hay, M.R.C.S.Eng., L.R.C.P.Lond., to Mary, daughter of the late Thomas Edward Mason, M.D., and of Mrs. Mason, The Limes, Deal.
- LYLE SELFE.** On July 31st, at Holy Trinity Church, Blackheath Hill, Herbert Willoughby Lyle, M.D.Lond., M.R.C.S., F.Z.S., elder son of Thomas Lyle, M.A., to Elisabeth Ada, eldest daughter of James D. Selfe, of Blackheath Rise.

## Deaths.

- WILKINSON.**—On August 7th, at Bernard Castle, Durham, after a very short illness, Thomas Lewis Wilkinson, M.D., of the Grange, Exmouth, in his 78th year.

### THE CAUSATION, PREVENTION, AND TREATMENT OF MISCARRIAGE. (a)

By PETER HORROCKS, M.D., F.R.C.P.,

President of the Obstetrical Society of London; Obstetric Physician to Guy's Hospital, London.

#### I.—CAUSATION.

THE term miscarriage is taken to include premature expulsion of the contents of a gravid uterus at any time from conception up to the end of the sixth month, before the fœtus is viable.

The term abortion is more commonly associated with criminal cases, and it is convenient to limit it to such cases. The proportion of miscarriages has been estimated at about 1 in 80 from hospital statistics, and at 1 in 5 from other statistics. In the statistical report at Guy's it was only 1 in 182. These estimates are of but little value, owing to the difficulties in obtaining accurate information. In all probability if all the instances could be collected, and particularly if it were possible to include very early miscarriages, the proportion would be even greater than 1 in 5.

Primiparæ are less likely to miscarry than multiparæ.

The possibility of pregnancy occurring at any time during an intermenstrual period with a miscarriage resulting at what would have been the first missed period is discussed, such miscarriages being spoken of as menstrual miscarriages.

The majority of known early miscarriages occur after one period has been missed, and such cases are mostly criminal.

The methods of criminal abortionists are mentioned.

Anything that disturbs the attachment between the fœtus and the mother may cause miscarriage. Hence increase of the intra-abdominal pressure from straining is one of the prolific causes.

These causes operate not only by separating the maternal and fetal parts of the placenta, and so causing uterine pains, but the blood may plough up the fetal parts of the placenta or the ovum, and so result in a carneous mole, and in later stages strains may actually rupture the membranes and so lead to miscarriage.

Shock and fright are causes, and the *modus operandi* is discussed.

In former days operations could often be done without disturbing the course of gestation. This is even more true at the present time, though occasionally miscarriage results.

Neighbouring diseases, such as fibroid tumours in

the pelvis, ovarian tumours, parametritis, perimetritis, Fallopian tube diseases, may cause miscarriage.

Tight lacing and great contraction of the pelvis, rectal diseases, and abdominal tumours interfere with the natural progress of gestation.

The rôle played by syphilis is discussed, and it is pointed out that as a rule the miscarriage is due to syphilis in the ovum, derived from the paternal element.

If a pregnant woman acquires syphilis after she has conceived, the child is not syphilitic.

Hydatidiform mole is described, and also fatty, calcareous, and inflammatory conditions of the placenta.

Excessive and scanty liquor amnii and malformations of the fœtus.

Deciduoma malignum is mentioned. Imperfect fertility due to extreme youth or age of one or both parents, or to debauchery or feebleness.

Affections of the umbilical cord, knots, shortness (disturbing the placenta), longness (round neck), &c. Diseases of the fœtus, causing its death, and so resulting in miscarriage. Endometritis, one of the commonest maternal causes of syphilis. Catarrhal endometritis with hydrorrhœa gravidarum described. The ill effects produced by criminal abortions and by methods adopted for preventing conception. The effect of sea voyages, sea sickness, &c., are discussed. Also, displacements of the uterus, blood diseases, convulsions, chorea, placenta prævia, cancer, over-suckling, deep fissures of the cervix, damage to the uterus, baths, alcohol, anæsthetics, habit.

#### II.—PREVENTION.

Avoid overstrain, shock, and fright. Operations not to be performed unless needful, especially extraction of teeth.

Avoid using instruments about uterus and cervix, and also avoid syringing. Pessaries should not be worn after the fourth month.

Purging should be avoided, and enemata, specially with turpentine or glycerine. Constipation should be avoided. Pelvic tumours may be pushed up into the abdomen or even removed. Endometritis must be cured. Cessation from coitus often permits of gestation progressing to term. Uterine displacements must be remedied. Avoid tight lacing.

Certain ecbolic drugs must not be given, such as ergot, savin, digitalis and quinine, lead.

Syphilis should be treated in both father and mother, and very often it is useful to give small quantities of mercury throughout pregnancy. General diseases must be treated with the appropriate remedies. Over suckling should be avoided.

Trachelorrhaphy sometimes enables the ovum to remain in the uterus.

(a) Abstract of paper read at meeting of British Medical Association, Cheltenham, August, 1901.

Alcohol should not be taken to excess, and in most cases should be avoided altogether.

High pyrexia from any cause should be brought down by cold baths, &c.

### III.—TREATMENT.

a. Avoidable. b. Unavoidable. c. Incomplete.

Rest in bed and some form of opiate the best treatment. If in doubt operate and clear out the uterus.

When there is serious hæmorrhage, or when os uteri is so large or expulsive pains so great and frequent that miscarriage is inevitable, allow it to take place, and, if need be, assist it either by puncturing the membrane or clearing out the uterus digitally under an anæsthetic.

When incomplete it is best to clear out the remainder. In some cases it is useful to pack the vagina with gauze. The bleeding is stopped or lessened, and uterine contractions are promoted, and later on it is much easier to deliver.

Vaginal injection of hot lotions are recommended by some, but they are not very trustworthy.

Dilators may have to be employed and ovum forceps and a curette, but it is better to mutilate the fœtus than to damage the mother.

Everything must be done aseptically, and if need be the uterine cavity must be swabbed out with tincture iodi or some other antiseptic.

## ASYLUMS AND ASYLUM WORK. (a)

By OSCAR WOODS, M.D. Dub.,

Resident Medical Superintendent, District Asylum, Cork.

AFTER cordially welcoming the members of the Medico-Psychological Society to the southern capital of Ireland, and thanking them for the high favour conferred on him by his election as President for the ensuing year, he said as this is the first meeting of the association in the Twentieth Century, I think that a short *resume* of what has been done for the insane, more especially in Ireland, during the century just closed would not be out of place, and afterwards I wish to point out what I hope will be effected early in the present one. The census report for 1851 stated that the first steps taken to provide for the lunatic poor in Ireland was in 1728, when the Lord Mayor of Dublin, Sir William Fownes, caused cells to be erected in the workhouse for the reception of lunatics. The Act 11 and 12 George III. (1772) was subsequently passed, enabling some provision to be made in workhouses for lunatics, but the first legislative enactment specially directed for the support of the insane appears to have been 27 George III., c. 39, which enabled grand jurors to present for the support of insane persons, and to provide wards for their reception in the county infirmaries. This Act was, however, little availed of. St. Patrick Hospital (Swift's) was founded in 1745, and at the opening of the 19th Century the only other provision existing for the care of the insane in Ireland was two institutions, known as Houses of Industry, one in Dublin, opened in 1772, the other in Cork, in 1787, the latter being the larger, giving accommodation for 425 patients, and admitting in the first twenty years of its existence 3,443 patients. The present Richmond Asylum, opened in 1815, grew out of the House of Industry in Dublin. In 1817 a committee was appointed to report on the state of the pauper lunatic in Ireland. It reported: "The common mode of treating the insane was when a strong young man is thus affected

the only way they have to manage him is by making a hole in the floor of the cabin, not high enough for the person to stand in, with a crib over him to prevent his getting out; the hole is about four feet deep. They give the wretched being his food in it, and then he generally dies." The friends did their best; the State had done nothing. The mode of treating the lunatics of this time was by confining them in wooden cells specially constructed for confinement and coercion. Hallam, writing about this time, says that most people believed in moon-madness, or, as described by the Irish, "Geal taigh cachet." Such then was the condition of the insane at the beginning of the last century. In 1817 nine asylums were ordered to be built, providing accommodation for 980 patients, at a cost of £204,000. In 1821 an Act was passed, enabling the Lord Lieutenant to direct any number of asylums to be built for such districts as should seem expedient, and when more than one county was included the asylum should be sufficient to contain not less than 100 or more than 150, but when only provided for one county a number of not less than 50. It was not till the 8 and 9 Victoria, c. 107, was passed that this legislation was repealed. The earlier asylums built were therefore all too small, and from that day to the present the Irish asylums have year after year been reported as overcrowded, notwithstanding that asylums have from time to time been built, and the older ones enlarged. At the present date there are 23 asylums, accommodating over 17,000 patients, and nearly all are overcrowded.

I extract the following information from the last report of the inspectors of lunatics; it is, however, arranged somewhat differently in order to show the number of lunatics and idiots at large in each census return. In 1851 the lunatics and idiots in asylums were 3,436; lunatics at large in workhouse and prison, 1,840; idiots ditto, 4,704; total not in asylums, 6,544. In 1901 the number of lunatics and idiots in asylums was 16,822; lunatics at large in workhouse and prison, 4,041. The number of idiots and lunatics at large, as returned in the last census is not yet available, but I have reason to believe it is not much, if at all, reduced. These figures show that there is still an ample margin for a large increase in the registrable insane without any increase in the occurring insanity. As a rule, all non-medical writers assert that lunacy is much on the increase, and one sapient statistician has calculated that in 400 years the sane people would be insufficient in numbers to put the insane safely under lock and key. However, the figures given above are such as to cause us to think seriously, and endeavour to suggest a remedy. If we deal with the registered insane alone, we find the following figures for the United Kingdom:—1859: Ireland, 6,734; England, 36,762; Scotland, 6,072. 1900: Ireland, 20,863; England, 106,611; Scotland, 15,663, or one registered insane person to the sane population in the following proportion:—1859—Ireland, 600; England, 535; Scotland, 505. 1900—Ireland, 213; England, 301; Scotland, 281. Thus, while in 1859 Ireland was the sanest portion of the United Kingdom, at the present time it has much the largest proportion of insane, having increased from 1 in 600 in 1859 to 1 in 213 of the same population in 1900. The population in 1859 was estimated at 5,861,711; by the last census return just issued it had been reduced to 4,456,546. This was largely accounted for by emigration to the United States, which country was glad to have our fittest and best, but took good care to return those who did not prove themselves mentally and physically sound, sending home those who showed the slightest symptoms of insanity, even after years of residence there.

It is very doubtful whether the latest attempt to

(a) Presidential Address delivered at the Sixtieth Annual Meeting of the Medico-Psychological Association of Great Britain and Ireland, held at Queen's College, Cork, July 25th and b, 1901.

deal with the chronic insane in this country will have good results. The Local Government Act of 1898, Section 76, made special provision for the care of the chronic and incorrectly-called harmless insane, but only provided a rate in aid of 2s. per head per week. This amount was, I am sure, fixed under a misconception, as the cost of 3s. 6d. per head mentioned in the Act, evidently referred only to cost for food incurred in many of the workhouses. A little agitation on the part of the Irish members could, I am sure, have this increased to 4s., and even if the local taxation account should fall short, which is possible, no Government could refuse to contribute the full quota to secure proper care for Irish lunatics. This provision of 2s. in the Act was evidently provided in order to better the condition of the unfortunate insane in the workhouses, who are admitted by all to be very inadequately provided for, but if the grant is not increased it will never be thought advisable to transfer patients from existing asylums where a rate in aid of 4s. per head per week is contributed to another institution where only 2s. would be received, even though it would be necessary to add inexpensive buildings to all the existing asylums. It is manifestly unjust to force on the County Councils the responsibility of providing for all the insane, and to lower the rate in aid per head from 4s. per week to 2s. for all in so-called auxiliary asylums.

It is unnecessary here to argue the important and much-vexed question as to whether primary insanity is on the increase or not; but as the number of registered insane is increasing and has to be provided for, every effort should be made to arrest if possible the progress of the disease. There is a marked difference in the type of insanity in Ireland and in Great Britain, for while a large number of the patients admitted into the asylums of this country are acutely maniacal, there is much less general paralysis and epilepsy. The prominent causes of general paralysis—syphilis, hard living, and intemperance—are much less potent in Ireland than elsewhere. Syphilis, which is so frequently the cause of general paralysis, is rare in this country, while in England and Scotland it is, at least in some districts, very common. Then the life led by the agricultural classes in Ireland is altogether different to the anxious, exacting, and toilsome life led by the lower classes in England and Scotland, especially in the cities and mining districts; and alcoholic stimulants, which, no doubt, contribute largely to this disease, are consumed in a very different way in the two countries. I can recollect no case of general paralysis ever coming under my notice in Ireland of an agricultural labourer who had not at some time been out of his own country. Soldiers, sailors, and occasionally members of the constabulary force are mainly the sufferers. Unless these reasons also account for the small proportion of epilepsy in Ireland I can give no explanation. The transmission of insanity by heredity is of importance, and we should aim at prevention in the near future by arresting heredity and encouraging in every way early treatment. Attention should also be devoted to providing hospitals for the treatment of the curable patients and villas for phthisical patients, and promoting pathological research.

1. The danger of transmitting insanity might be greatly lessened by more judicious marriages. I could give you case after case of the patients who have been more than once in an asylum entering into marriage shortly after discharge. Of course, such cases were almost bound to break down again, and to propagate children defective from birth, or who would develop insanity at some important epoch of life. In some districts in the south and west of

Ireland it is almost unknown for a man to select a wife outside his own circumscribed valley or neighbourhood, and this dislike to bring in new blood had very evil results. In some districts almost all the people have the same name, and another has to be added on to distinguish the families. I do not think it would be impossible to take steps, both medically and legislatively to arrest to some extent heredity. This was a matter of vital importance if they were to retain their present position among other nations, and of absolute necessity to the prosperity of the country. Typhus, fever, small pox, diphtheria, had been almost stamped out by sanitary precautions. Typhoid fever and other diseases are largely prevented by inoculation. Why, then, should not every possible step be taken to prevent the most pitiable, the most expensive, and to a nation the most degenerating of all diseases? It might be declared illegal to discharge any man or woman from an asylum during the procreative period of life unless perfectly recovered. Marriages of discharged patient ought not only to be discouraged, but under certain circumstances prevented by law, and practising physicians ought to be more alive to the danger of the neurotic, and those predisposed to insanity, contracting unsuitable marriages. Many would say they could not interfere with the liberty of the subject, and that restrictions of this kind were out of the question, but if this evil was not anticipated and dealt with more acutely than at present insanity must go on increasing.

2. The necessity for early treatment has not been sufficiently recognised either by the public or by law; nearly 50 per cent. of the insane are kept at home until they become a source of danger, thereby considerably lessening the prospect of their recovery, and acting as a means of propagating insanity and transmitting disease. I think it will be accepted that 45 per cent. of those admitted to asylums may be classed as incurable; many of them rendered so because they have not sooner been put under treatment, the friends looking on asylums as prisons, and believing patients cannot be sent in until they commit some indictable act, and except in very acute cases keeping them at home till they become dangerous to themselves and those about them.

3. A greater effort should be made to deal with premonitory symptoms, to watch those with hereditary predisposition at the critical periods of life, and establish hospitals throughout the country, where neurotic patients of all kinds could be treated. It should not be necessary to wait till certificates can be signed. Many asylums in England are now opening out-door departments; if this could be carried out I believe the loss of many valuable lives by suicide would be prevented, and the actual number coming under certificates would be lessened. Greater provision should also be made in all asylums for the separation and treatment of curable patients. I do not think any patients regarding whom there is a possibility of cure should be allowed into a ward with chronic patients, but should be separated in small wards, according to their mental condition, and placed in charge of fully-trained nurses in the proportion of at least one to five. A great step in advance has been made in the recently constructed English and Scottish asylums, but I hope before long every asylum admitting acute cases will have its detached hospital for curable patients, very much on the lines planned for East Sussex, and so lucidly explained to us last year by Dr. Hayes Newington. I presume it will be admitted that in the majority of asylums not more than 5 per cent. of the population are curable, and for them money ought to be spent ungrudgingly. It is difficult to treat properly acute mental cases, many of them of the most nervous temperament, in the wards of a chronic asylum, but

less expensive buildings than most of the English modern asylums would, I think, suffice for the care of many of our demented patients.

4. When we find that the death-rate from phthisis varies from 17 to 40 per cent. in asylums, it is surely necessary that more active steps were taken to arrest a disease which is now generally recognised, with proper precautions, to be preventible; no doubt the insane are specially prone to it, and it is very difficult of detection without the careful observation of both physicians and nurses, but with early recognition, complete isolation in suitable villas with a maximum of sunlight and open air, and a thorough disinfection and destruction of all bacilli, much might be done to stamp out a disease infectious and, in a well-organised institution, largely preventible.

5. Pathological work will, I trust, take its proper place in asylums, and the good example shown by the London County Council and Scotland be followed in other districts. At present an effort is being made to legalise the appointment of a pathologist for the Irish Asylums, and will, I hope, bear fruit at an early date. The Chief Secretary, in reply to a deputation that waited on him recently, acknowledged the necessity; with his sympathy and aid I hope the difficulty will soon be got over, and that the various asylum committees will quickly co-operate and appoint men of the fullest experience to carry out a work of vast benefit, not only to the present, but to future generations, and to the nation at large.

But these recommendations mean money, much can be done in England and Scotland that cannot be attempted in Ireland, and it may not be out of place here to quote a sentence from the report of Dr. Curwin, Superintendent of the Warren Asylum, U.S.A., who not long ago visited this country, and, referring to Irish Asylums, wrote: "It is earnestly and sincerely to be hoped that the English Government which has the control and direction of all matters concerning the expenditure for such institution in Ireland will awaken to the urgent necessities of the situation, and extend a helping hand and a generous support to the most dependent of its people by the provision for more extended means for their relief and maintenance."

Although the English Government has not the control and direction of matters concerning the expenditure, I fear much must remain undone till more liberal aid is given by the Government for the insane poor. Lunatics have a special claim on the State. Why should not the example which has been set with such good results by the American Government be followed, and asylums be supported altogether out of State funds?

This change was inaugurated in the United States on October 1st, 1893. What are the results, and what was almost the first recommendation of the Commission? "That all State hospitals which are not already provided with suitable facilities for specialised individual treatment of recoverable cases, provision be made for the erection and equipment of small hospitals, sufficient to accommodate about twenty-five patients, with their attendant nurses, one building for either sex, and that these buildings be supplied with everything in the way of structural arrangements, and medical appliances and equipment, that may be regarded as necessary to ensure to their inmates the highest degree of medical skill and treatment." The State Commission also made provision for the pathological research of the most complete kind recognising that the pathology of insanity is not definitely established, and of the great advantage that medical science, and through it the general public, would derive from a correct knowledge of this subject, which might be applied not only to the cure, but also to the prevention of mental disease, the Commission feels that the importance of this recom-

mendation can scarcely be overstated. Now what is the result of this important change? Dr. Wise, President of the State Commission in Lunacy, giving his experience of five years' working, states that the State Care Act "will ever stand as a monument of the progressive spirit of our commonwealth." He quotes one superintendent who was opposed to the change, but who now writes, "In all that pertains to the care and treatment of the insane, whether it be in structural provision, equipment, a high standard of repair, nursing and personal attendance of patients, the medical service and scientific inquiry and observation, the personal liberty and diversion of patients, and all that tends towards their cure, contentment, and comfort, the quality, the preparation of food; to the physiological curative needs of the insane, the clothing of the patients, and in all other things this hospital has progressively and steadily advanced its standard under the present system, and I truly believe this applies to all the other hospitals in the department of insanity."

Testimony such as this is abundant, and while there is a unanimity of opinion that the standard of improvement has been raised by 50 per cent., it has been effected at a reduction of the cost of more than 20 per cent. Dr. Wise is so enamoured of the good done that he concludes his pamphlet in the following words: "Like planting and cultivating will produce an equally rich harvest in all institutional work for charity, reform, and correction." This is indeed remarkable, and very strong testimony, and ought not lightly to be set aside; we live to learn, and in a poor country such as this, State aid cannot be too liberally dealt out to the most afflicted of all God's creatures. Whatever legislation decides as to the future of the insane, we must not forget that we have committed to our charge those unable to assist themselves. We are in all cases their guardians and guides, let us then endeavour to do our duty so that it may be said of us as Shakespeare said of the faithful servant:—

"O good old man, how well in thee appears  
The constant service of the antique world,  
When service sweat for duty not for meed.  
Thou art not for the fashion of the times  
When none will sweat but for promotion."

## THE USE OF DRUGS IN PULMONARY TUBERCULOSIS. (a)

By W. R. HUGGARD, M.A., M.D., F.R.C.P.,  
Davos Platz, Switzerland.

IN regard to the use of drugs in pulmonary tuberculosis there is much difference of opinion among medical men. By some physicians drugs are considered either useless or harmful; by others one drug or method of treatment is considered *the* treatment. Creosote, cinnamate of soda, arsenic, formaldehyd, and various other drugs have each their devoted adherents, who regard their pet remedy almost as a specific. A large number of medical men, while not discarding drugs altogether, employ them only for the relief of urgent symptoms.

All these views are, in my opinion, too narrow; some over-estimating the power of drugs, and others over-estimating their limitations. From another standpoint, also, the foregoing views are too narrow. The great variety in the clinical forms of phthisis is dropped out of sight; and the same line of treatment in regard to remedies is sometimes adopted without sufficiently precise reference to the case in hand.

(a) Paper read before British Congress on Tuberculosis, July, 1901.

The object of this paper is to point out some of the advantages that may be gained by the judicious use, and some of the evils that arise from the injudicious or indiscriminate employment of drugs in pulmonary tuberculosis. The broad principles will also be indicated which determine my own selection of remedies according to the variety of the case. The subject is one in which the comparison of individual experience is of the greatest value in extending our knowledge, and in putting it on a firmer basis.

The first point to be made clear is that up to the present no specific has been found for tuberculosis. Not merely so; but there is no drug that is useful in all cases. Nevertheless there are various drugs that favourably influence the course of some varieties of the disease always provided that they are well tolerated by the patient, and that they do not cause any disturbance of appetite, digestion, or assimilation. Time does not permit even a hasty review of all the drugs useful in phthisis. The various conditions only that indicate or contraindicate one remedy rather than another will be rapidly considered.

What medicines have we at our disposal? Drugs may favourably influence the course of the disease—

1. By improving the general health; as, for example, arsenic, quinine, strychnine, lime, phosphorus preparations.
2. By increasing the local resistance of the affected tissues, as creosote and its derivatives, salicyl preparations, and counter irritants.
3. By modifying the quantity or character of the secretions, as the balsams, the terebinthines, the essential oils, morphine and apomorphine, and inhalations, especially of formaldehyd.
4. By controlling systems that react prejudicially on the patient. Among these are—

(a) Digestive ailments. (b) Excessive or needless cough, which shakes and exhausts the patient, causes fever, or prevents sleep. (c) Scanty expectoration and retention of secretions. (d) Fever, which spoils appetite, and prostrates the patient. 5. By removing complications, such as syphilis.

In the choice of remedies the points to be considered are not the same as guide us in diagnosis or in prognosis. The first and most important point to recognise is, that treatment by medicines must be altogether subordinate to general hygienic management—good food and fresh air with rest and exercise, according to the individual needs of the patient.

The first and most important point in treatment is to consider the state of the digestive system. If the stomach or digestion is out of order drug treatment is, as a rule, inadvisable, except in so far as it may aid in restoring the digestive functions to a normal state, or in removing some condition that tends to prolong the digestive ailment. For example, appetite and digestion not uncommonly improve with the artificial reduction of temperature, or with the control of excessive cough. In such cases we must feel our way cautiously and be guided tentatively by the results. The most important indication then is to get the stomach and bowels into proper working order. Nothing goes right so long as the digestion is wrong.

Temperature is the next most important guide to treatment. Pyrexia will in a large proportion of cases yield to absolute rest, bodily and mental, combined with life in the fresh air. In many cases, however, a return to a normal level of temperature can be hastened by the administration of small doses of phenacetin—one to three grains—in combination with quinine and salol and sometimes arsenic. Taken in this way phenacetin seems to have rather a tonic than a prejudicial effect on the heart and on the general health, and may without hesitation be continued for months if need be. My experience of other antipyretics, save for occasional use, has not been so favourable, with the exception perhaps of salipyrin.

Arsenic, quinine, and salicyl preparations greatly diminish, in my opinion, the tendency to recurrent attacks of subacute inflammatory character and those recurrent febrile attacks without any change in the physical signs which are so marked a feature in a large number of patients suffering from pulmonary tuberculosis. These recurrent febrile attacks are no doubt of very various origin, tubercle as a rule rendering the organism highly sensitive to influences that cause pyrexia. The drugs I have mentioned seem to me to diminish this sensitiveness to febrile reaction. In doing so they accomplish something more than the avoidance of a temporary drawback or inconvenience. In tuberculosis, more than in any other disease, slight drawbacks are apt to provoke further prejudicial effects, and each morbid condition tends to become chronic. In averting slight drawbacks, therefore, we avoid great dangers which might completely alter the course of the disease. The disease is one in which pre-eminently anything short of the best is bad.

Next to pyrexia, as a guide to treatment, I would place a marked tendency to hæmoptysis. Creosote and guaiacol increase, in my opinion, the liability to pulmonary hæmorrhage—as well, in fact, as to pulmonary inflammation—and should be avoided where such a disposition is present. The lime salts, the terebinthines, and the balsams have, I believe, on the contrary a somewhat restraining influence, as has also morphine in minute doses.

The treatment of excessive cough requires much judgment. A closely allied object of treatment is the modification and, as a rule, the diminution of bronchial and pulmonary secretion—the “drying up of the lungs.” A certain amount of cough is in a large number of cases indispensable, and has a salutary influence. The problem is to secure the removal of the pulmonary and bronchial secretions with the least amount of virulence, exertion, or fatigue for the patient. Sometimes the secretions are extremely abundant, sometimes too scanty. The balsams and the terebinthines and tar for the most part diminish bronchial secretion, and the terebinthines commonly render it at the same time less tenacious and easier to get up. Minute doses of morphine—from one hundred and twentieth to one sixtieth of a grain of any of its salts—diminish secretion, but as a rule render it more tenacious. Apomorphine in small doses—one-twentieth to one-sixteenth of a grain of the hydrochlorate—loosens the secretion without making it much more abundant. The recently introduced morphine derivatives, heroin and dionin, greatly diminish cough, and to some slight extent diminish expectoration, while they are free from the drawbacks that morphine has, of rendering the secretion viscous and difficult to get up. They are also practically devoid of constipating effect, and they do not upset the digestion. For the last two or three years they have almost altogether replaced in my practice the phosphate of codeine, which has fewer drawbacks than has morphine for the relief of excessive cough.

The most valuable agent that I am as yet acquainted with for modifying the bronchial and pulmonary secretions is the vapour of formaldehyd. For the last three years I have used this drug extensively, and with more and more satisfactory results. When steadily used it generally causes the secretions to be less purulent and more mucous, at the same time diminishing the amount and rendering expectoration easier. Where the use of the drug has been steadily persisted in for months, tubercle bacilli have, as a rule, also become less numerous, and in some old cases even have disappeared. The mode of employment requires a little care. The best way, in my opinion, to use formaldehyd is by means of a muzzle inhaler. The strength of the solution should at first

not be more than two or three per cent. in rectified spirits of the ordinary forty per cent. solution. The addition of some essential oils renders the inhalation quite agreeable. Only from five to ten minims at first should be put on the inhaler, and this quantity should be renewed every fifteen or twenty minutes, the entire time of inhalation being from two to four hours a day. The strength may be gradually increased up to 6 or 8 per cent., and sometimes even to double that amount. If cough is very irritable, chloroform may be added to the inhalation. From independent observations I am strongly of opinion that chloroform, apart from its soothing influence on the cough, has in some cases a beneficial influence on the disease. It must, however, be used with judgment. I have known it seemingly give rise to pyrexia, by causing retention of secretion. The inhalation of formaldehyd on the contrary tends considerably to diminish pyrexia due to the absorption of toxins. Formaldehyd has another advantage. If not too strong, it diminishes irritability in the pharynx and larynx. It is, however, very irritating to the eyes and nose, and for this reason should be used only with an oral inhaler, or if the Burney Yeo oro-nasal inhaler is employed, it should be placed below the nose.

According to my experience syphilis is a complication of pulmonary tuberculosis in a much larger proportion of cases than is usually thought. In such cases I consider the treatment of the syphilis to be of the first importance. Small doses of the perchloride of mercury have then, instead of a depressing, a remarkably tonic influence. Intra-muscular injections of mercurial salts, though more strikingly beneficial, have as a rule the drawback of being excessively painful. To this rule, however, *huile grise* or mercurial ointment, rubbed up with sterilised oil, is an exception. The iodide of ethyl inhalation is perhaps the least objectionable, while not the least efficacious mode of giving iodine. It may be combined with the formaldehyd inhalation.

To sum up, then, my line of treatment is determined, in the first instance, by the digestive system, by the general health, and by the state of nutrition.

If digestion is bad the only drugs indicated are such as will restore it to a normal condition. If digestion is good, the general condition satisfactory, and the patient improving, I refrain from using drugs unless some definite indication is present. Among the most important indications for drugs are persistent afternoon pyrexia in spite of absolute rest out of doors; a tendency to recurrent febrile attacks or to slight inflammatory attacks. This tendency is usually combined with impaired nutrition and with a low state of general health. In these conditions arsenic, strychnine, quinine, and salol are among the most useful tonics. Active softening, excessive cough, overabundant expectoration, and, more rarely, scanty expectoration, expectoration of extremely purulent or nummular character, require attention; and the drugs useful for these conditions generally seem to me to have a favourable influence on the course of the disease in addition to the temporary relief from discomfort they may afford. Among such drugs are formaldehyd vapour, creosote and its derivatives, except the carbonate of guaiacol, which has generally seemed to me to be inert, terpin hydrate, oil of cinnamon, myrtol, the balsams, and the lime salts. In sluggish chronic softening, counter-irritation by iodine or by small flying blisters is of the greatest use. When an old syphilitic taint is present its removal should be our first care.

The short time at my disposal does not permit a detailed examination of the points I have brought forward, and my remarks are rather to be considered in the light of heads for discussion than as

even a partial exposition of the subject. What I have said may, however, I trust, be sufficient to induce others to bring forward their experience on the same lines.

## INOCULATION AS A PREVENTIVE AGAINST TYPHOID FEVER. (a)

By HENRY M. CULLINAN, L.R.C.P., L.R.C.S.I.,  
L.M. Rotunda Hospital,  
Senior Assistant Medical Officer, Richmond District Asylum,  
Dublin.

In venturing to write on the subject of preventive inoculation against typhoid fever—a measure of treatment which, so far, is on its trial, and which can hardly be said to have been yet adopted by the medical profession—I should like to preface my remarks by stating that, in presenting the result of my experiences gained in the inoculation of over five hundred female patients in the Richmond Asylum during the recent epidemic of enteric fever, I lay no claim to have made a discovery, and it is possible that, had my opportunities for testing the efficacy of this treatment fallen into other hands, more interesting results might have been forthcoming. At the same time I have considered that the conclusions to be drawn from the occurrence of this epidemic in the Richmond are interesting, and justify me in placing before you the result of my observations, principally in the hope that any discussion which my remarks may give rise to will be of practical utility, and draw from those present suggestions which may guide us in the preventive treatment of this disease.

The epidemic referred to occurred in the Asylum last year, extending over some five months, and was of considerable severity. There had been cases of enteric with long intervals between each for about a year, but in August last the number of cases began to assume the proportions of an epidemic. When eighteen cases had occurred within three weeks it became evident that a serious state of affairs existed, and Dr. Conolly Norman, Medical Superintendent, obtained from Professor Wright, of Netley, a supply of lymph, which he has introduced for inoculation or vaccination against enteric fever. On receipt of this I commenced operations, and inoculated in rapid succession 307 female patients, inoculating each patient once only with  $\frac{3}{4}$  c.c. of the serum, commencing on September 6th and finishing on October 3rd. I had then operated on all the patients who lived and slept in the portions of the Asylum which were considered infected areas. It was suggested to me by some enthusiastic medical friends that I should vaccinate only one-half of the patients in each ward, in order to see if the other half would contract the disease, but I did not feel justified in adopting this course, however interesting the result might have been; on the contrary, the cases were becoming so numerous that our only anxiety was to inoculate everybody as rapidly as possible. However, unintentionally, I did, in fact, experiment, inasmuch as we did not inoculate any of the nurses, and it will be observed that in proportion to their numbers our staff suffered much more severely than the patients; also, having completed the inoculation of these patients, comprised in certain wards, and numbering, as stated, 307, the operations were stopped, and it was not until November 5th, when it was found that the wards which had not been gone over, and which had been looked on as immune, began to contribute cases, and severe cases, to the number attacked, that I again

(a) Read before the Section of State Medicine of the Royal Academy of Medicine, Ireland, April 28th, 1901.

started and inoculated the remaining patients in the house, by which I mean all those of 55 years and under that age.

The most interesting and important point in these experiments is, of course, to determine whether the vaccination confers any immunity against typhoid fever. I have come to the conclusion that it is of the utmost value in this respect, and I hope I am not incorrect in forming that opinion, deduced as it is from the records kept of the dates in which cases occurred and the very important and practical fact that out of a total of 511 patients inoculated only seven contracted the disease, and almost all of these were, in my opinion, in the incubation stage when inoculated. As already mentioned, eighteen cases had occurred when the vaccination was commenced on September 6th. Of these, ten were patients and eight were nurses. Owing to want of hospital accommodation we were able to operate on only forty patients at a time, and as these were kept three or four days in bed it took some time to go over them all.

While the inoculation was in progress—that is, from September 6th to October 3rd—nine fresh cases occurred, of which only three had been operated upon. Of these three there is no doubt that one was actually in the early stages of the disease at the time of inoculation, as, owing to an oversight, her temperature was not previously taken, but was found to be 101° immediately after the operation, remaining high and at once assuming the characteristic curve of enteric fever. Case No. 2 was found to have normal temperature, and was apparently in good health before inoculation. The temperature rose after the operation, but instead of coming down in a few days, persistently remained high and assumed enteric features almost at once, and, as immunity is said not to be conferred until from three to five days have elapsed after inoculation, I think it may be concluded that she would have contracted the disease in any case. The third case was inoculated on September 22nd, and on the 24th was quite well apparently, but on the 28th was found to have a temperature of 100°, and a couple of doubtful rose spots. On the 30th there was a typical crop of spots, and the case from that out was a severe one, complicated later on by double pneumonia, from which, however, she recovered, and has since left the Asylum.

I would not place this case definitely among those suffering from prodromal signs at the time of inoculation, but allowing three or four days to the serum to confer immunity, and as the spots began to appear six days after the operation, I think we may fairly refrain from blaming the lymph. A girl who had been inoculated on October 3rd, having left hospital three days after vaccination, was attacked very severely on October 15th. She was found on this date to have a crop of spots. This patient, I regret to say, died. It must be remembered that in an asylum patients are frequently walking about with a high temperature and severe symptoms unknown to the medical staff and without complaint; and it is only when they get very ill that they are noticed to be so. Accordingly, it is difficult to determine when this patient began to be the subject of enteric fever.

On November 5th, owing to several cases having occurred among patients not inoculated, I resumed operations, and vaccinated 204 females, making a total of 511. I am much indebted to my recent colleague, Dr. William Starkey, for his assistance in inoculating a considerable number of these patients.

On November 14th a patient who had been inoculated on September 22nd—nearly eight weeks previously—and had been quite well in the interval, was found to have a most profuse crop of spots. This is an example of a case in which the serum failed to do its work, and it also exemplifies the fact that lunatics

will often walk about with a severe disease attacking them, seemingly in normal bodily health, as this woman only complained of feeling ill when she actually exhibited the spots in great numbers. Another patient, inoculated on November 12th, was very ill after the operation, and continued so with a high temperature. On the 20th she had a crop of spots, having had all the appearance of typhoid in the interval. This may, I think, be considered a case in which the patient was sickening for the disease at the time of inoculation.

Another woman, about fifty years of age, operated upon on November 5th, and getting over the effects in three days, was found on November 17th with a temperature of 101°, and had a very severe attack, followed by a relapse, from which she nearly died. I consider that on this occasion the serum acted detrimentally, and probably accentuated the severity of the attack.

In order to prove the efficacy of serum inoculation as a preventive measure it is necessary to show that those treated were living at the time within an infected area. This was undoubtedly the case in the Richmond, as, although the place was thoroughly overhauled by the Public Health Authorities, and a new system of drainage laid down with great promptitude, cases continued to occur with persistent regularity, mostly among the staff—a total of seventeen nurses being attacked, of which nine contracted the disease after the inoculation of patients commenced, none of the nurses having been operated on. Twenty-eight inmates were attacked during the inoculation process, of whom only seven had been operated upon—showing that during this period thirty-seven cases had occurred, proving conclusively that the source of infection still existed. The last case which occurred was a girl admitted about five weeks when she was attacked, a fact which adds weight to this statement.

The question might be asked, Would these patients who were inoculated and escaped the disease have contracted it had they not been inoculated? This, of course, I am not in a position to answer, and it would, I think, be quite impossible to ascertain. The fact remains that they *were* inoculated and *did* escape.

With respect to the constitutional disturbance following inoculation it did not prove in any of the cases in my experience to be of great severity. In every case, almost, the temperature rose within a couple of hours, in some few instances reaching 103° and 104° the day of operation, while 101° and 102° were common heights for it to attain. It usually fluctuated for a couple of days, coming down gradually from the maximum, and being generally normal on the third day. In every case operated on four-hour temperature records were kept. Except in the cases already specially mentioned the patients were able to be up and about on the fourth day. The principal symptom was headache, from which eighty-five suffered, some of them very severely. Vomiting or retching occurred in sixty-three cases, loss of appetite and refusal of food in thirty-three, diarrhoea in two, rather severe prostration in three; four complained of abdominal pain, while stiffness in the back and soreness over the seat of inoculation occurred in nine and twenty-two cases respectively. The last symptom—soreness in the flank, where each patient was vaccinated—was not in any case accompanied by local manifestation beyond slight redness of the part, with some swelling.

I should have liked to have been able to compile a table in which the agglutinative action of the blood serum of each patient on the bacilli before and after inoculation was shown, but unfortunately the rapidity with which cases occurred created something of the nature of a panic, added to which, coming on during

the vacation season, we were handicapped as regards medical assistance, for which reasons the inoculations were performed as quickly as possible without first examining the blood, except in a certain number of cases, not very large. On examining the reaction of the serum in these cases, I found that in every instance there was a certain amount of clumping of bacilli, in some much more than others, but in no case did I find the remarkably thick clumping which is shown in the blood of patients actually suffering from enteric. I believe that the fact of our patients only having been inoculated once contributed to this lessening of the Widal reaction, as Dr. Wright recommends a second inoculation about twelve days after the first, but, as already stated, we were unable to carry this out. Although from a pathological point of view this omission to inoculate a second time is unfortunate, I think it proves clinically more conclusively the usefulness of the lymph, as there is no doubt our patients were exposed to infection during the entire period of the process.

I append a short table showing the ages of those attacked, distinguishing those inoculated and those not inoculated; also the ages of all who were inoculated, whether attacked with the disease or not. The result, in brief, shows that of a total of 655 who were liable to be attacked fifty-four contracted the disease—i.e., 8.24 per cent. Of the 511 patients inoculated seven, that is 1.36 per cent., were attacked after the operation. Forty-seven cases occurred, not having been previously inoculated, that is 7.16 per cent of the total liable to infection.

Age.	15	20	25	30	35	40	45	50	Total.
	to 20	to 25	to 30	to 35	to 40	to 45	to 50	to 55	
Inoculated ...	9	35	107	83	149	59	48	21	511
Contracted disease ... (previously inocul't'd)	—	2	1	3	—	—	—	1	7
Contracted disease ... (not previously inoculated)	1	16	6	6	8	7	2	1	47
									(7.16)

In connection with this table I should point out that I have made no distinction in it between the nurses and the inmates who were attacked. In looking at these two classes of patients separately it must be allowed that the insane are more liable to be attacked than the sane by a disease like enteric; their mode of life and general environment, taken together with their mental disability, render them peculiarly susceptible to any disease which is rife. Judging the results of the inoculation from this point of view (and this should not be overlooked in arriving at a decision) we find that 17 out of 114 nurses, or 14.9 per cent., were attacked, none of the nurses having been operated upon; while 37 inmates out of a possible 541 liable to attack, or 6.83 per cent., were the subjects of enteric. That is to say, more than double the percentage of sane and robust people, none of whom were inoculated, were attacked, as compared with the percentage attacked among the inoculated, all of whom were, owing to their insanity, more likely to suffer from physical ailments.

In conclusion, I should be sorry to make any dogmatic statements as to the absolutely preventive action or otherwise of inoculation against typhoid fever. If one can credit the results as evidenced among the soldiers in South Africa, enormous numbers of whom were vaccinated, it would appear to have been somewhat of a failure. There may have been circumstances in their case which militated against the success of the procedure. I cannot help thinking that it was of use in the epidemic in the

Richmond, but I shall be glad to hear the remarks of more experienced physicians than myself, who, though they probably have not had an opportunity of testing the lymph to the same extent as I have, can bring clearer views than mine to bear on the question.

## Paris Clinical Lectures.

### MEDICAL TREATMENT

OF

## CANCER OF THE STOMACH.

By CHARLES ROBIN, M.D.,

Professor of Clinical Medicine, University of Paris.

[REPORTED BY OUR PARIS CORRESPONDENT.]

[FOR FIRST ARTICLE See MEDICAL PRESS AND CIRCULAR, July 24th, 1901, page 8.]

I WILL complete to-day the medical treatment of cancer of the stomach by the consideration of remedies which relieve the symptoms and prolong the existence of the patients.

These remedies are directed either to the predominating symptoms or to the accidents which are apt to occur in the course of the malady. The symptom which immediately attracts the attention of the medical attendant to the existence of cancer, especially in elderly patients, especially if at the same time they are pale and emaciated, is anorexia or loss of appetite.

This anorexia soon merges into a positive *disgust* for food, and it is a most distressing symptom. If we know how to avail ourselves of the various means at our disposal we may be almost sure of stimulating the appetite of these unfortunate patients. As the remedies employed for this purpose are extremely numerous and vary greatly in respect of their nature and effects, I will divide the symptoms into three groups, having regard to their intensity, viz.:—Slight anorexia, pronounced anorexia, and total anorexia.

In the first series the first agent I employ is *quassia amara* in infusion, and it is on the whole a very successful treatment. If at the end of a week the appetite has not returned I have recourse to *mengante*, or water clover, which, like gentian, is usually employed in the form of a maceration. I prefer giving it in the form of wine; one drachm of *mengante* in a pint of boiling claret, and allowed to infuse twenty minutes. It is then strained and left to cool. The patient takes half a tumbler of the preparation before meals. If neither of these remedies gives satisfaction, I order tincture of *nux vomica*. In pronounced anorexia I give, a quarter of an hour before meals, a cachet containing five grains of chloride of ammonium, two grains of Dover's powder, five grains of bicarbonate of soda, and a quarter of a grain of powdered *nux vomica*.

In grave cases of anorexia remarkable results may be obtained by two new drugs, on which I read a paper recently before the Therapeutical Society, viz., persulphate of soda and metavanadate of soda. The first is given according to the following formula:—

Persulphate of soda, xv grs.;  
Water, ℥v.

A teaspoonful before the two principal meals.

Each teaspoonful contains two grains of the salt, a dose which should not be exceeded. As soon as the appetite returns the treatment should be suspended, otherwise, as Hirtz pointed out, a painful and distressing sensation of hunger is created. The persulphate given under these conditions succeeds in two-thirds of the cases.

Metavanadate of soda is even more active, and should be substituted for the preceding when, after

eight days the desired result has not been obtained. It must not be forgotten that it is a powerful tonic, and requires to be administered with prudence. The dose should not exceed one-fiftieth part of a grain, given twice a day.

Metavanadate of soda, 1 gr. ;  
Water, ʒx.

A teaspoonful represents one-fiftieth part of a grain ; two daily before meals.

By one or other of these means we shall probably succeed in restoring the appetite to the patients. But this is not all ; the patient must be able to digest what he eats. These patients secrete little or no hydrochloric acid, consequently the judicious exhibition of pepsine and hydrochloric acid is calculated to give satisfactory results. I employ a solution of hydrochloric acid (2-1,000) of which the patient takes a wineglassful in sips during the meal. I insist on this detail, which, however insignificant, has its importance ; in fact, we must endeavour to reproduce as exactly as possible the conditions of natural digestion. Now, we know that hydrochloric acid is not secreted all at once but gradually, as the food is being digested, consequently the liquid must be introduced into the stomach progressively and not in one dose at the end of the meal. The same rule applies to pepsine. It is my practice to give during the meal from three to five of the following cachets :—Pepsine, 6 grs. ; maltine, 2 grs. As a general rule, pepsine is prescribed in too small quantities, for we must remember that under normal conditions the stomach secretes enormous quantities of pepsine ; consequently, we ought always to give from twenty grains to a drachm of pepsine and two or three pills of pancreatine. The patient then should take in sips during the repast a wineglassful of hydrochloric acid (2-1,000), and four or five cachets, containing each ten grains of pepsine and two grains of maltine, and at the end of the meal two or three pills containing two grains of pancreatine.

If the artificial digestion is accompanied by irregular fermentations provoking pain, this symptom must be treated according to its nature. When the fermentation is lactic, I prescribe fluoride of ammonium, 5 grs. ; water, ʒx. Of this solution the patient will take a tablespoonful during the meal, or we may give a cachet containing iodide of sulphur, 2 grs. Such is the treatment of anorexia, dyspepsia, and gastric fermentations in patients suffering from cancer of the stomach. There is another symptom, more frequently met with, however, in gastric ulcer, which will require your attention and that is pain. The following mixture will be found useful in such cases :

Cocaine } aa 1 grain ;  
Codeine }  
Lime water, ʒv.

A dessertspoonful to be taken when the pain supervenes.

I have also been in the habit of prescribing instead of the mixture a cachet as follows :

Lactose, xv gr. ;  
Calcined magnesia, xxx. gr. ;  
Subnit. of bismuth } aa xij gr. ;  
Prepared chalk }  
Codeine, ½ gr. ;  
Bicarb. of soda, xv gr.

I must not omit to call your attention to a not infrequent accident, viz., hæmorrhage. Naturally, hæmorrhage has not the same importance in cancer as in ulcer of the stomach, but it must be borne in mind that frequent coffee-ground vomiting exhausts the patient and must be treated. Against this we may prescribe :

Tartaric acid, 5 to 10 grains ;  
Powdered opium, ½ gr. ;  
Calcined magnesia, ii grs.

For one cachet : one to be taken before each meal. If this does not succeed, which is rare, you can try against the vomiting :

Picrotoxine, } aa 1 grain ;  
Morphia, }  
Sulphate of atropine, ½ grain ;  
Ergotine, xx grs. ;  
Cherry laurel water, ʒiij.

Five or six drops about ten minutes before eating. If, however, no treatment succeeds, solid food must be suppressed, and the patient confined to milk diet.

Such are the indications and the rules for the medical treatment of cancer, and the results will be found to be to a certain extent satisfactory. Out of twenty-five patients thus treated, ten increased in weight, and their lives were prolonged by several months ; the average was 422 days.

Before closing I must say a few words in regard to the surgical treatment of cancer of the stomach, which comprises pylorotomy on the one hand and gastro-enterostomy on the other. As regards the results of these two operations, it would appear from statistics that the improvement obtained in the condition of the patient is often greater than that from medical treatment ; life is also more prolonged, the average being 507 days. Consequently each time that it is possible to diagnose cancer of the stomach at an early stage you will advise pylorotomy. As to gastro-enterostomy, which consists in establishing a communication between the stomach and the intestine, the results are less favourable, the improvement for the patient being more transitory, and the average gain in the patient being only 209 days.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 17th, 1901.

At the Free Society of Surgeons Hr. Sonnenburg first of all alluded in suitable terms to the loss the Society had just sustained in the death of its honoured member, Hr. Langenbuch, after which Hr. H. Oppenheim related a case of

### TUMOUR OF THE SPINAL CORD.

The patient was a gentleman, æt. 40, who first consulted him in September last, complaining of pains in the left hypochondrium corresponding to the region supplied by the seventh and eighth dorsal nerves. The pains had been present for two and a half years, and in spite of all known remedies had steadily got worse. The patient's bearing was stiff, there was no kind of deformity observable in the spine, and no tenderness on pressure. On examination it struck the speaker that the patient's umbilicus was drawn a little to the right, the muscles of the left side appeared to be flabbier than the right, but it was difficult to be certain as the patient was fat. The muscles on the left did not react to faradisation, and the reflex on that side was absent, whilst it was distinctly marked on the right. A tumour was suspected on account of the duration and intensity of the symptoms, but as there was a possibility of a developing spondylitis a corset was applied. When the patient was again seen the symptoms had become worse. He could still walk, but there was weakness of the legs. There was now thermo-anæsthesia of the right leg, as well as diminished sensibility in the painful parts. Extension treatment was now begun, under which symptoms of pressure rapidly developed.

On November 12th there was complete paraplegia.

On the right the sensory and on the left the motor symptom most marked. There was retention of urine, girdle pain, and spasm in the lower extremities, and further a slight swelling of the soft parts in the region of the seventh and eight costo-vertebral articulations.

On November 17th the canal was chiselled and a tumour found at the level of the sixth vertebra and shelled out. It had grown from behind and pushed the cord on one side. The longest diameter of the tumour was 3.5 cm. It was a myxoma with partial myxomatous degeneration. The after course was at first favourable. The girdle pain ceased in twenty-four hours. In four days the urine was passed spontaneously, sensibility and motor power improved. Some days later, however, fever of an intermitting character developed, and the patient died on the eighteenth day of ascending meningitis. The cord showed a very slight constriction, but the microscope revealed ascending degeneration and diffuse disease at the site of the compression.

Hr. Sonnenburg made some technical observations, and thought the unsuccessful termination of the case was due to the temporary resection. He had the impression that the vertebral arches acted as foreign bodies and irritated the wound, whereby the outflow of spinal fluid was impeded. He would advise that the resection should not be temporary, that the first dressing should be kept on a long time, and that only the upper layers should be changed as soon as they were soaked through.

Hr. Israel had brought a case of chiselling of the spinal canal through, although meningitis did come on, and he attributed the good result to not making the resection temporary. It was a case of complete paralysis from fracture of the vertebral column. On opening the canal he found a large quantity of fluid above the compression, but none below it. A lamella of bone was found to be the cause of the compression. This was removed, and during the process of removal the dura was torn. For a week things went on well, and then symptoms of meningitis set in, with a good deal of purulent discharge from the dural sac. The dressing was renewed as often as it got soaked through, and this he thought essential, and the child pulled through. The paralysis was not relieved.

Hr. Sonnenburg discussed the subject of

#### APPENDICITIS AND TRAUMA

from a medico-legal point of view. Whether an injury could set up appendicitis had been decided by Bramann to the effect that it might if the appendix harboured a coprolite. The speaker, on the contrary, believed that trauma could excite inflammation only when the process was previously altered in structure.

The following case was very instructive:—A woman, who had had pains off and on for a long time had violent pains after a slight injury. This recurred several times, and after two years and a half led to extirpation of the appendix. Near the tip of this were found some coprolites, the mucous membrane in a state of catarrhal inflammation, and fixed by adhesions. These adhesions were caused by hæmorrhage following the injury. It was remarkable that when a trauma occurred where perityphlitis was present, the result did not correspond in severity to that of the injury. Previous disease of the process was necessary for trauma to set up peritonitis.]

Hr. v. Bergmann confirmed the views of the previous speaker.

Hr. Muhsam spoke on the

#### DIFFERENTIAL DIAGNOSIS BETWEEN APPENDICITIS AND TYPHOID.

A man was taken suddenly with obstruction, vomiting, and abdominal pain, and after temporary improvement was sent into hospital. The sensorium was then free, temp. 38.2, pulse 88. The abdomen was soft, but slightly resistant in the ileo-cæcal region. No splenic tumour and no roseola. In a few hours the symptoms became so much worse that gangrene of the appendix was suspected and laparotomy performed. The omentum was attached to the appendix, and a piece of the cæcal wall had slipped between the adhesions. The wall of the bowel was thinner at this spot, the remainder of the cæcum swollen. The mesenteric glands were also swollen. The adhesions were separated. A week after the laparotomy roseola and splenic tumour made their appearance, but neither bacteriological nor chemical test showed evidence of typhoid until the tenth day, when Purekowsky's test gave a positive result.

Hr. Sonnenburg related a case of

#### [ACUTE GANGRENOUS APPENDICITIS IN A GRAVIDA.]

Vomiting, pain, and distension set in in a woman five months pregnant. Resistance was found in the right side independent of the uterus. Laparotomy was performed, and the appendix was found gangrenous at the tip; stinking pus behind the uterus. The appendix was removed, the abscess emptied, and recovery took place, with abortion following some weeks later.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 17th, 1901.

#### FOREIGN BODIES IN THE THROAT.

SPIBA, of Cracow, in his review of Polish work, relates a number of interesting cases. The first, a female, was admitted to hospital under Dudrewicz, with a peculiar history. While at a meal she swallowed some bread which gave her sharp pain. Shortly after she began to vomit, which rather increased the pain when endeavouring to swallow, more particularly on the left side which was tender to pressure, the pain being increased with coughing, which was accompanied with hoarseness. A week later there was blood in the sputum and saliva.

After this, a careful exploration of the larynx was made, with special attention to the seat of pain. The internal surface of the larynx was greatly swollen, more particularly the left side, and left false vocal cord. Between the Santorini and Wrisberg cartilages on the left side, just over the processus vocalis, was observed a gray coloured point which turned out to be the head of a pin. Cocain ewas applied to the inner surface of the larynx to bring down the swelling. A later examination revealed a red line below the vocal cord, indicating the presence of a foreign body. With the assistance of a pair of long forceps the head of the pin was secured and extracted, being 32 m.m. long, or 1.3 inch. The point of the pin, which was evidently swallowed with the bread, seems to have been lying free in the trachea, which would increase the pain in vomiting.

**PRIMARY INFLAMMATION OF THE MASTOID PROCESS.**

Heiman, of Warsaw, informs us that, according to his experience, very few primary cases of periostitis of the mastoid process go on to suppuration. All that do occur are of a traumatic origin, although he has had one that arose from erysipelas. All the cases he has met with have ended in resolution or thickening of the periosteum arising from severe exposure to cold, syphilis, or rheumatism. A number of the so-called primary periostitis are in reality secondary to otitis media externa or inflammation of the soft tissues in the immediate neighbourhood.

A primary periostitis of the mastoid process may be diagnosed by a hard, painful, well-defined swelling over the process, while the skin, soft tissues, aural passage, tympanum, and middle ear, are found to be perfectly healthy.

According to Heiman, primary inflammation is a very rare occurrence, although Politzer affirms that this in the mastoid process is not uncommonly met with. Injury, cold, and syphilitic origins usually commence the trouble, the inflammation of the periosteum in the cavum tympani extending later to the mastoid process. It may easily be understood from this argument that primary mastoiditis is more theoretical than clinically practical, and, furthermore, when we are told by Heiman, whose wealth of experience is extensive, that he has not met with a single genuine case, we must infer that it is a very rare occurrence.

**WASHING THE PHARYNX AND LARYNX.**

Heyng is a firm believer in the gargle, but the patient must be taught with small quantities at first to take it well back by inclinations of the head and allowing it to return by the nasal passage. The fluid should be cold at first and warm after. Ice must not be administered because of the danger of introducing microbes into an already morbid passage. Three or four ounces of the gargle should be used for five minutes at a time to be of any service, this acts on the mucous membrane as hydropathy to the skin. As a prophylactic it is indisputable when epidemics of scarlet fever, diphtheria, angina, &c., are prevalent.

There are many cases where this form of treatment is contra-indicated, such as post-diphtherial paralysis of the soft structures glosso and labiopharyngeal, and recurrent paralysis, perforation of the hard or soft tissues, perichondritis, &c., &c., where the patient has no control over the fluid and where the spray is useful. He divides the medicamenta into antiseptica, antispasmodica and narcotica, adstringentia, and resolventia. Of the antiseptics the best is a sublimate solution of 1 in 2,500; next comes salicylate and boracic, 1 in 200, and thymol, 1 in 1,500.

Zawadzki has recently been experimenting with insoluble powders and gargling with methylene blue or washing out the powders with simple water. His results were that the pharynx was never reached with a gargle, the tonsils sometimes, and the mouth always.

**KOPLIK'S SPOTS IN MEASLES.**

Strzelbicko draws attention to the diagnostic importance of "Svor" or patches on the tongue, of which Filatow first drew attention, and which recently has been confirmed by Koplik, whose name they now bear. In the late epidemic of measles in Tula eighty-four out of every 100 had well marked Koplik patches; in fifty-nine

other cases they were present forty times; in thirty cases, eighteen times; and in twenty-one cases every one. The coloured patches are not to be found on the conjunctiva or nasal membrane, only on the tongue, and this is characterised as the measles tongue. It is more evanescent than the scarlet fever tongue.

**The Operating Theatres.****KING'S COLLEGE HOSPITAL.**

**REMOVAL OF A TUMOUR FROM THE BRAIN.**—Mr. LENTHAL CHEATLE operated on a woman, *æt.* 34, who had been admitted under Dr. Aldren Turner. The patient had suffered from fits for five years; she had also complained of headache. Recently they had increased in frequency and were accompanied by left hemiplegia. They always began by slight twitchings of the angle of the mouth on the left side, spreading from thence to the rest of the face and to the left side of the body, and then the convulsion became general—evidently a typical case of Jacksonian epilepsy. Optic neuritis had been lately rapidly developing. There was some pain on thumb pressure over the right Rolandic region. These symptoms led Dr. Turner to believe there was a cerebral tumour, probably of simple nature and situated in the lower part of the right Rolandic region, and the following operation was undertaken for the removal of the growth:—A flap was turned down exposing the right side of the vertex of the skull by means of a curved incision beginning behind the external angular process, extending to the middle line at the top of the skull, and ending at the external occipital protuberance. This flap was turned down and then wrapped in cyanide gauze wrung out in 1 in 2,000 warm perchloride of mercury solution. The pericranium was then reflected, and a trephine inserted at a point where the fissure of Rolando joins the Sylvian fissure; a circular piece of bone was removed, and the trephine hole enlarged by means of bone forceps. The dura mater looked opaque and white towards the region of the frontal lobe. This appearance of the dura mater caused the operative procedures to be extended towards the frontal lobes, and necessitated turning down another flap of skin from the frontal region. Upon incising the dura mater after removing more of the frontal bone the underlying brain was incised and the finger inserted. No abnormal condition could be detected, therefore the right Rolandic region was more thoroughly explored by removing more bone. These procedures demonstrated a tumour, the surface of which was flat, hard, and superficial. It had a somewhat pearl-like appearance, its edge being abruptly demarcated from the surrounding convolutions. It measured two inches in its longest diameter (which was in a longitudinal direction), and about one inch and a half in its widest diameter. The dura mater was very slightly adherent to it. Upon reflection of the dura mater the encapsuled tumour was easily separated from the surrounding cerebral convolutions. In doing this the right lateral ventricle was opened, and cerebro-spinal fluid escaped. Only one arterial branch required ligature, bleeding from other parts being easily arrested by applying the blunt end of a needle at dull red heat. The opening into the lateral ventricle was not sutured as the convolutions fell so naturally into apposition; the dura mater was sewn up, the skin sutured, and the wound dressed

in the ordinary way. Mr. Cheatle said the success of the operation had depended entirely on the accuracy of the diagnosis originally made by Dr. Turner. The first symptoms that suggested the presence of a tumour were the left hemiplegia, the optic neuritis, the pain on thumb pressure over right side of the head, and the fits. The fact of these last beginning at the left angle of the mouth and then becoming general pointed to the tumour being in the right lower Rolandic region. Mr. Cheatle remarked that the tumour from the slowness of its growth and its encapsulation was probably benign, but that if it were sarcoma it was in all likelihood not of a malignant form, and he thought that the simple removal of the growth without any portion of the surrounding convolutions would be all that was necessary towards the ultimate cure of the patient.

It is satisfactory to state that a week after operation the woman is doing well, all her former symptoms having completely disappeared. There has been no rise of temperature.

#### CANCER HOSPITAL.

INGUINAL COLOTOMY FOR CARCINOMA RECURRING AFTER EXCISION OF RECTUM AND VAGINA.—Mr. CHARLES RYALL operated on a woman, *æt.* 48, who had been admitted into the hospital complaining of painful and difficult defæcation. Two years ago she was taken into the same institution suffering from malignant disease, implicating the lower rectum and the posterior vaginal wall; the diseased parts were then removed by the dorsal incision, sacrificing the coccyx; healthy rectum was brought down to form the posterior vaginal wall, and the new anus was placed beneath the sacrum. From this the patient made an excellent recovery, and was discharged from hospital; she had kept well until recently. She now complains of great difficulty in passing a motion, which is accompanied by great straining and much pain. There is a copious and constant discharge of mucus, with considerable loss of flesh. On examination the anal orifice was found to be stenosed from cicatricial contraction, and on introducing the finger a large new growth could be felt on the right side blocking the lumen of the bowel without any apparent destruction of mucous membrane. The vagina seemed practically normal, but in the posterior cul-de-sac could be felt the new growth which was implicating the rectum. Colotomy was considered a necessity owing to the obstruction. Eight inguinal colotomy was performed, the muscle fibres of the abdominal wall being separated and not divided. The sigmoid loop was drawn out, and a spur fixed in position by double sutures through the mesentery and abdominal wall, a single suture at either end of the wound securing the longitudinal muscular band. The bowel was not opened at the time of operation. Mr. Ryall remarked that there was no necessity to stitch the peritoneum all round the incision to the bowel, as strong adhesions took place even in a few hours, and the bowel could be opened with perfect safety if there was any distension; but patients, he said, are generally able to wait for two days before this is done. At the end of a week the stitches would be removed and the spur cut off level with the skin, after which a colotomy plug would be worn. He said that the recrudescence of the original disease was a disappointment, as the patient had kept well for nearly two years, and he drew

attention to the posterior vaginal wall which had been formed of the rectum at the first operation, and which felt like a normal vaginal wall.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 21, 1901.

#### SCHOOL BOARDS AND SANITATION.

THE announcement of a change in the terms of the appointment of the medical officer of the School Board of London affords a fitting opportunity for discussing the general relations that exist between educational bodies of that kind and sanitary administration. The immediate cause of the retirement of Dr. W. R. Smith from the London Board is that he could not agree with the condition attached to a rise in salary, namely, that he should “hold no other appointment except that now held by him as Professor at King’s College.” The merits of that particular demand we do not propose to discuss here, but content ourselves with the remark that the magnitude and importance of the interests involved seem sufficiently great to require the whole time and energies of any single officer. But apart from that issue there are various important points that will repay consideration. The work of the medical officer may be divided into the care of the health of teachers on the one hand, and of that of the children on the other. Candidates for teaching are properly required to come up to a fair physical standard, which is usually determined by the Board medical officer, who may or may not be required to attend the teaching staff medically during illness. The main part of his function, however, is preventive, that is to say, he has to look after the proper construction and sanitary environment of the school buildings, and to adopt measures with a view to prevent the spread of infectious diseases. In approaching this subject it should be borne in mind that the school board system is comparatively modern, so that the development of any sound system of sanitary supervision would naturally require years

of experience. It is clear that the bringing together of large numbers of children, especially in the crowded centres of population, at once multiplies greatly the chances of propagation of communicable diseases. Most public health authorities are agreed that the disastrous spread of diphtheria in recent years has been mainly due to the aggregation of children in board schools. Whether that be the case or not, it may fairly be asked what steps have been taken by the London School Board to exclude scholars suffering from sore throat. The medical officer of health may be unsparing of his energies in eradicating diphtheria from his district, but his efforts may be checkmated by the counteracting influence within his boundaries of certain board schools, where medical supervision is lax or altogether absent. This conflict of central and local health authorities is to be deprecated, as the board school is only too apt to fall to the ground between the two stools. We have always maintained that the district sanitary authority should have absolute control over the scholars so far as infectious disease is concerned, and over the sanitation of school buildings. The Salvation Army night shelters were shown to be a danger to the public health, and only after years of legislation were brought under the control of the local authority. The board schools of London have for a long time past been an acknowledged danger to public health, but they still remain under a central medical administration that apparently has never quite realised its responsibilities in the way of guardianship of the physical welfare of the scholars. The case of ringworm abundantly illustrates that retrograde position. The disease prevails to an enormous extent in the board schools of London, but we have yet to learn that any steps have been taken by the Medical Department of the Board either to eradicate or exclude the malady. There can be no doubt whatever that ringworm is spread to a degree that is well-nigh incalculable by the agency of the board schools. That fact can be testified to by all who have any experience of special hospitals for diseases of the skin or of skin departments at the general hospitals. So far from attempting to exclude children suffering from ringworm, the officers of the Board seek by every means in their power to bring pressure upon parents to send such children to school. A crop of prosecutions is directed weekly against those responsible for sufferers of that class. It is open to question whether under a carefully supervised medical system it would be possible for children suffering from this obstinate, troublesome, and costly complaint to attend school. Then, again, there should be some systematic method of excluding all doubtful cases of sore throat, to say nothing of granular lids and other infectious disorders. On the whole, it seems likely that nothing short of systematic daily medical inspection would suffice to maintain a high preventive standard. If the London School Board do not see their way to adopt a system of that kind it is to be hoped that, in their readjustment of the medical side of their

administration, they will at least take steps to remedy some of the grosser defects to which we have called attention. To maintain the wholesomeness of school buildings, and to exclude as far as possible the invasion of communicable diseases, is not the least important part of the duties of a school board, more especially in dealing with the population of the richest and largest city in the world.

#### GASTROECTASIS OF CHILDHOOD.

EVERY physician, at some time or other in his practice, meets with gastroectasis in the adult. Its diagnosis is comparatively easy. He has the history, the well-known symptoms, and his principal concern is the treatment. But when the disease occurs, as it does sometimes, in children, particularly in strumous ones, where the dyspeptic troubles are not easily traced to a state of gastroectasis, the disease is likely to be overlooked. Few medical writers on children's diseases refer to it, withal the proneness of children to dyspepsia from getting unwholesome food should put us on our guard and make us look for such. We are apt to forget that the disease is not always attended with either pain, closure of the pyloric orifice, or cancer. That it may occur suddenly and cause death in a few days without giving rise to any of the usual symptoms of the disease, even in an adult, is shown by the case of Watson and Bright, in which the patient died on the eleventh day of her illness, and the cause of death was only recognised at the examination of the body, although the stomach reached to the pubis and had given way in several places. Malnutrition and nerve innervation are more powerful factors in producing gastroectasis than pyloric narrowing; and such conditions are the outcome of dyspepsia, particularly in city-reared children. We are inclined to think that the disease would be seen to be more often noted if the cause of death in childhood were more frequently verified by post-mortem examination. In childhood vomiting is not so frequent as a symptom of the disease as it is in the adult, simply because the malnutrition of the muscular walls leaves them incapable of throwing out its contents. When the effort to vomit is made it usually ends in partially expelling the contents through the patulous pylorus, the child utters a faint cry and falls back exhausted. The belly is tympanitic, the tongue coated, the bowels irregular, often purged, the stools being liquid, with an acid, sour, fœtid smell, and the breath according to the stage of the dyspepsia may give off the smell of acetone, butyric acid, caproic acid, or sulphuretted hydrogen. If the child is stripped and placed on its back the epigastrium will be seen to rise or rather be jerked forward, from time to time as the over-distended stomach tries to empty itself into the duodenum. The wasted little body offers no difficulties in the examination, and the incessant feeble cry of pain which soothing syrups and carminatives fail to

stop, tells how much the child suffers. The condition now rapidly runs from bad to worse, for as the digestive function is more and more disordered, the natural stimulus of normally digested chyme is wanting, and the pyloric sphincter irritated by the decomposed stomach contents contracts; the contents remain bottled up in the viscus which they enlarge by distension, and the fungi, the germs of which were swallowed in the food, now finding a suitable menstruum for their growth, react injuriously on the mucous membrane. The difference between gastroectasis and dyspepsia is more one of degree than of quality; the conditions that produce dyspepsia will, if persistent produce gastroectasis. In every case the food must be such as the child can digest, and the environment of the child must be such as promotes its general health, and great care must be taken to ensure a complete convalescence after the acute diseases of childhood. We find that in the recorded cases the history of one went back to an attack of small-pox; in a second case the tardy convalescence from typhoid fever was blamed; in a third, anæmia. But the most interesting of these is M. Leven's case (Soc. Anat.) of a child nine years old, whose stomach reached to the pelvis and seemed to occupy the whole belly; the child was tuberculous, got an attack of pleurisy, from which she died, and the post-mortem examination revealed the gastroectasis, which had been unsuspected for years. Two things conspired to produce the disease in this case, to wit, the anæmia, and marasmus of the tuberculosis, and the mechanical pressure of the swollen lymphatic glands which surrounded the pylorus, and were found in the course of the gastro-duodenal artery and the hepatic. To increase the difficulty of diagnosis the disease may be closely simulated by congenital stenosis of portions of the alimentary canal as Brinton taught at the beginning of the Nineteenth Century. The lesion usually manifests itself soon after the child commences to get solid food—when it may be mistaken for intussusception or hernia. In a recent case the little patient, a girl two years old, had the principal symptoms of gastroectasis, and yet the post-mortem examination revealed a congenital narrowing of the ileum near its middle, and enormous distension of the jejunum and upper half of the ileum.

### Notes on Current Topics.

#### The Eyelid Symptoms in Exophthalmic Goitre.

THERE are two peculiarities of the movements of the eyelids met with in connection with Graves' disease to which more or less diagnostic importance is attached. Under ordinary circumstances the upper eyelid follows the movement of the globe when this is turned downwards, but in the subjects of this disease the eyelid lags behind or descends by jerks. This is known as Von Graefe's sign. It is to be noted that the upward movement of the lid does not usually present any peculiarity. Stellwag's

sign, first described by him in 1869, though it had previously be noticed by White-Cooper and Dalrymple, consists in a retraction of the lids, thus increasing the dimensions of the palpebral fissure through which the sclerotic may be visible all around the sclero-corneal margin. This retraction is most marked in the upper lid, though the lower lid also participates in the process. Both these signs exist quite independently of the exophthalmos, indeed they tend to become less marked in proportion as the proptosis becomes more evident. It must be noted also that even in cases of extreme retraction the lids, in the absence of a mechanical obstacle due to the prominence of the globes, can always be closed by a voluntary effort, only the unconscious movements being thus affected. It is difficult to estimate the diagnostic value of these eyelid symptoms in the absence of trustworthy statistics as to their frequency and duration. When present they are probably very significant of the malady, but their absence by no means negatives its existence. The origin of these signs is as yet imperfectly understood, but they have been attributed to changes in the oculomotor nuclei, a view which is supported by the comparative frequency in exophthalmic goitre of paresis of the external ocular muscles, especially of the internal recti.

#### Mirror Writing.

THE so-called mirror writing is the normal spontaneous effort to write with the left hand of a person accustomed to write with the right hand. This tendency applies equally to all movements acquired by the right hand. Without any special education the left hand reflects as in a mirror the gesture of its right fellow, so that we are driven to the conclusion that there has been a process of unconscious education of the left extremity *pari passu* with that of the right member, in other words that the training of the centre for the right hand has been reflected *en miroir* on the cortical centre for the other limb. It has been suggested that this fact should be turned to account in the case of persons who are deprived of the use of the right hand by encouraging them to adopt the plan of mirror writing with the left hand in preference to the tedious acquisition of the ability to simulate right-handed writing. It is asserted, moreover, that this training has for effect to favour the functional reintegration of the damaged centre on the other side. It is interesting to note that the readiness with which persons write *en miroir* with the left hand is in direct proportion to the extent to which they have trained the right hand. Persons of defective education, in whom the tracing of each letter entails a distinct effort of the will, are incapable of writing with the left hand, even *en miroir*, whereas those accustomed to write with fluency adopt this alternative with comparative ease.

A NUMBER of children were poisoned at Dukinfield last week from eating laburnum seeds, but the prompt administration of emetics proved successful in averting a fatal result.

### What are the Marks of a Bite?

THE question of how a wound has been inflicted is often a crucial point in medico-legal cases. The nature of the injury often affords satisfactory evidence as to the way in which it has been caused, as, for instance, when grains of powder are embedded around the entry-perforation of a bullet. At a glance it is possible, as a rule, to say whether or not the damage has been caused by a bite. The double semi-circular row of lacerations may be aptly compared to the indented marks left by an attempted bite from a hard, green apple. That there are fallacies about circumstantial evidence of the kind, however, is made abundantly clear by a recent police-court case in London. Two medical men attached to a general hospital testified that the injuries sustained by a woman were due to a bite. The chief point was the indented wounds were on both the back and the palm of the hand, and could have been caused only by pressure on both surfaces alike. Had the wounds been caused by a blow with a jagged instrument, or a stick studded with spikes or nails, only one surface would have been indented. On the other side a medical man swore positively that the wound was not due to a bite. While he admitted that the marks were something like teeth-marks in their grouping, yet from their position the teeth could not have caused them unless the assailant had the whole hand in his mouth, because of the position of the convexity of the arc. Moreover, the two series of marks did not correspond. No answer to these objections was forthcoming from the first-mentioned witnesses, and the magistrate came to the conclusion that an assault had been committed, without passing an opinion upon the conflicting medical testimony.

### The College of Safe Medicine.

THE attention of the Apothecaries' Society may be called to a certain J. C. Purdue, who figured last week at a Limehouse inquest. A baby taken to and treated by that person subsequently died of pneumonia. The bottle of medicine given to deceased was labelled "J. C. Purdue, F.C.S.M., London. Safe Medicine. Member of the Magnetic and Botanic School of Safe Medicine, London. Founded 1893. Advice gratis daily." In answer to the coroner, Mr. Wynne Baxter, Purdue stated that he was a "registered herbalist," and he explained that he made that statement on the strength of his name appearing in "Kelly's Directory." From his own admission it appears that he has been carrying on his nefarious occupation in the same neighbourhood during the past ten years, and has figured in no less than five inquests. With such a record of public experience it is nothing short of a social scandal that piratical practices of this kind should be permitted to continue year after year. In the course of his evidence Purdue alluded several times to a Dr. Meadows, and when questioned as to why he did so replied that if anyone took a child to that gentleman and said he had been to Purdue he would say "If he

can't do you any good, I can't." We should be loth to believe that any duly qualified practitioner of medicine countenanced in any way quackery so disgraceful as that of the College of Safe Medicine. We prefer to think that the bringing in of the medical man's name was simply a part of the tissue of chicanery and bluff that form the stock in trade of men of Purdue's stamp.

### Holiday Funds and Sick Children.

A SERIOUS defect in the working administration of a country holiday fund was disclosed last week in a London inquest. From the evidence it appears that a boy was sent home from a village in Huntingdonshire practically in a dying condition. On the journey he was unable to speak, and the railway guard gave him water several times. He was suffering from peritonitis, and subsequently died while undergoing an operation at hospital. The woman under whose care he had been placed stated that he had been ill for three days, and she sat up with him the night before his departure for London. She had not called in medical assistance, and had received no instructions as to what she should do in case of illness. The secretary of the society produced a copy of rules, one of which provided that if a child fell ill the country visitor should be informed at once. In this particular case he knew nothing of the woman with whom the boy had been lodged, as his dealings were with a woman of another name. This evidence points to laxity in an important matter affecting the safety of the children committed to the care of the Fund. The movement which affords town children a few days' holiday in the country is so altogether admirable that it would be a great pity were its usefulness curtailed by an oversight which appears to be one of administration rather than of organisation.

### Adrenal Therapeutics.

THE employment of adrenal extract bids fair to become a very important therapeutical departure. Experience has shown that the gland is possessed of very active physiological properties as a cardiac stimulant, and hæmostatic and contemporaneous medical literature affords ample evidence of its value in various directions. We alluded some weeks since to the possibility of remedying the non-coagulability of the blood which is the characteristic feature of the condition known as hæmophilia by the administration of the extract, and it has been successfully employed to combat uterine hæmorrhage. Its efficacy in arresting epistaxis is really remarkable, and for this purpose it is best applied on a swab or by means of a spray. It has been stated to have a marked effect in promoting uterine contraction, but this apparently does not obtain when given in therapeutical doses, for a case was recently published in which the extract was given to a pregnant woman to check bleeding from the nose and gums without any undesirable effect on gestation which went to full term, although some five ounces of the solution

of adrenal was given during the last three weeks of pregnancy.

#### Medical Research in Ireland.

THE question of medical research has been brought actively before Parliament during the last week of the Session, and in one direction with a most satisfactory result. On August 8th, Mr. William Johnston asked the Chief Secretary to the Lord-Lieutenant of Ireland whether, having regard to his reply to the deputation which waited on him in Dublin concerning a proposal to establish a pathological laboratory devoted to research in connection with insanity for the asylums of the country, he could introduce a clause into the Local Government (Ireland) Amendment Bill empowering county councils to contribute towards the support of such a central laboratory for the study of mental pathology. Mr. Wyndham replied: "Such a clause could not be inserted in the Local Government Act Amending Bill, but it would be germane to the Lunacy Bill now before the House. I earnestly hope to be able to introduce an amendment of this character into the latter Bill." It is most satisfactory to be able to record that on August 14th, on the motion of Mr. Wyndham, the following clause was inserted in the Lunacy (Ireland) Bill, viz:—"The committees for any two or more distinct asylums may agree to unite in providing and maintaining a laboratory for pathological research in connection with insanity and nervous diseases, and may defray the expenses incurred in pursuance of an agreement under this section by contributions from the funds at their disposal for the maintenance of the respective asylums." The fact that this clause was inserted in the bill without any opposition, shows that it is probable that advantage will be taken of it; indeed, we understand that many County Councils have been deterred in the past from devoting a portion of their funds to such an object solely by the fact that it was not in their legal powers to do so. We trust, however, that before any two or three asylums rush into a scheme for starting a conjoint laboratory, they will first unite with the other asylums in discussing the possibility and advantages of a grand central laboratory for the whole of Ireland.

#### Typhoid Fever in Belfast.

THE recently published minutes of the Public Health Committee of Belfast gave a serious picture of the extent and lethal character of the present epidemic of typhoid in that city. The Medical Officer of Health, Dr. Whitaker, tells in plain figures the growth of the epidemic which is very alarming. During the past month 306 cases of typhoid fever were notified, and the disease from being localised has come to prevail all over the city. Two things appear to account for the epidemic: the bad water supply and the deficient sewage arrangements for this rapidly growing and great city. The inhabitants are now fully alive to the evil, and with commendable energy the Public

Health Committee are taking steps to remedy the faulty sanitation, and get a pure water supply. And not one minute too soon, for it is an opprobrium to find that 167 deaths from such a preventible disease as typhoid fever took place there during last month. It is a difficult matter to ensure efficient sanitary arrangements in the large number of artisans' dwellings that the city contains, and to not unduly interfere with the necessary growth of such houses which the ever-increasing population of the city demands. A new water supply has now become a necessity, and altogether the condition is one calling for immediate treatment by some well considered scheme of sanitation. The citizens will have to face a heavy outlay. Belfast can be made a healthy city, as Hamburg has been made, and we have every confidence that the public spirit of its citizens will be found equal to the task.

#### The Late Small-pox Epidemic in Glasgow.

GLASGOW has now a clean bill of health so far as small-pox is concerned, the last two cases of that disease having been dismissed from Belvidere Hospital a week ago. The total number of cases has been 1,850, and of these 230 proved fatal. In connection with the late epidemic a useful object lesson has been taught the citizens of that large commercial city, as well as all other large centres of population, of the efficacy of re-vaccination in stamping out a loathsome and fatal disease. Free vaccination still obtains in Glasgow, and should be so in all large cities whether small-pox does or does not prevail. Dr. Chalmers, the Medical Officer of Health, is expected to issue a special report on the late epidemic which will be of a very interesting and instructive character. The accounts for re-vaccination have just been paid by the Corporation. In one instance a medical man received a cheque for over £300. Several accounts were over £200, and a number were over £100. The total cost has been considerable, but it is generally conceded that the money has been advantageously spent.

#### Government Grants for Scientific Investigation.

IN the House of Commons last week, Mr. Field asked the Chief Secretary for Ireland (1) whether he was aware that the English Local Government Board had at its disposal a yearly grant of funds for the purpose of promoting scientific investigation; and (2) seeing that the Irish Local Government Board had not at its disposal any sum for a similar purpose, would he recommend the placing of the Irish Local Government Board in this respect on the same footing as the similar Board in England? Mr. Wyndham replied that the vote for the English Local Government Board contained provision of a sum of money for "auxiliary scientific investigations" in connection with the medical department of the Board. He was at the time inquiring as to the special objects with which this money is voted; until he received information on this point he was unable to

reply to the suggestion in the second paragraph. We fancy that many boards of guardians would like to determine at the expense of the State what minimum amount of food per diem it is possible for a Poor-law medical officer to live upon, with the object of thus reaching the irreducible minimum of salary for the post. But apart from such purely philanthropic inquiries there are many useful problems to the solving of which money at the disposal of the Local Government Board could be devoted. *En passant*, if the English Local Government Board has a yearly grant at its disposal, would it not be spent very suitably in solving the question of the relationship of bovine and human tuberculosis?

#### Sea-Sickness and its Prevention.

THE question of sea-sickness will weigh heavily upon the mind of many a traveller during the present holiday season. This is the age of exhibitions, so we are often told, but surely there was never a more curious excuse for an "Exposition" than that of sea-sickness preventives, to be held next month at Ostend. The number of drugs vaunted for the prevention and the cure of that malady are legion, but for all that the surgeon on board ship still lacks a specific for his distressed patients, although he may afford a little relief here and there by carefully-selected remedies. Of mechanical cures there have been not a few launched by ingenious inventors upon this troubled sea of *mal de mer*, but the sea-sickness still continues in unabated flood. It is somewhat strange that the real inwardness of this familiar and distressing stomachic upheaval still remains one of the unravelled mysteries of the medical world. Perhaps the most plausible theory of causation is that which attributes it to the disturbance of the localising and balancing function exercised by the delicate semicircular canals of the inner ear. In the name of sea-sick humanity we wish hearty success to the Ostend Exhibition.

#### The Connection of Nasal Disease with Cataract.

THE importance of nasal diseases with regard to cataract is a subject which has up till now only been slightly touched upon. Professor Zieni, of Dantzig, says in the August number of the *Journal of Laryngology, Rhinology, and Otolology* that it may be assumed that by correct treatment of disease of the nose, not so much by bloodless galvano-cauterisation, especially of the middle turbinal, but by the withdrawal of blood from the nose, by the removal attended with loss of blood, of obstructive swellings or polypi, by syringing of the nose, by counter-irritations in the post-auricular space, and last but not least by the removal of febrile processes, the further development of cataract will straightway be prevented. Granting the assumption that the development of a cataract can be brought about by obstructed purulent disease of the nose as by other factors such as diabetes, &c., it would have to be further established whether the obstruction in the nose by itself would be able to accomplish the

clouding of the lens, or whether it would require the presence of a purulent disease of the adjacent cavities. The formation of cataract in such cases would have to be looked upon as being due to infection, or in some cases it would appear necessary that there should exist in addition some acute febrile trouble invariably connected with diseases of the nose, notably, for example, influenza. A striking illustration of the possible significance of febrile diseases in the etiology of cataract is to be found in the frequency of opacities of the crystalline lens in countries where febrile infectious diseases are of an endemic character, such a tract of marshy woodland for instance, as the "Sunderbunds," and also the district of Galicia. Much, no doubt, could be written on this theme, and perhaps, in the course of time, we shall live to see "Ophthalmology" added to the sonorous title of *Journal of Laryngology, Rhinology, and Otolology*.

#### Summer Diarrhœa.

IN many parts of the United Kingdom the scourge of summer diarrhœa is playing havoc among the infantile town population. In Manchester, for instance, last week's returns gave no less than 115 deaths from that malady out of a total of 316 deaths from all causes, and of the 115 diarrhœa deaths 95 took place under twelve months of age. In the same town the mortality from the epidemic in question reached 192 in the previous week. At the neighbouring township of Salford the returns for last week showed fifty deaths due to summer diarrhœa. Urmston, a residential suburb in the neighbourhood, presented a striking, not to say a startling, contrast, by having no deaths at all, either from diarrhœa or any other cause. As things stand at present the recurrent prevalence of epidemic diarrhœa is one of the gravest problems that demand the attention of public health administrators. Much has been learnt as to the bacteriology of town environment and also of the disease itself as it affects the human alimentary canal. For all that an immense field of research remains comparatively unexplored in the domain of comparative pathology. It seems likely that the key to the position lies in the direction indicated in the Milroy Lectures of 1899, namely, in the relation of town dust charged with bowel bacteria of the horse to the specific contamination of air, food, and dwellings.

#### Ankylostoma Embryos.

IN 1898 the fact was published by Dr. Looss that ankylostoma embryos can enter the skin of the human being, chiefly by the hair follicles. Dr. Looss happened on this discovery quite by accident. While engaged at laboratory work at the Cairo Medical School a drop of pure culture of ankylostoma embryos fell on to his hand. He examined the drop a few minutes later, and to his surprise he discovered numerous empty sheaths of embryos, the embryos having evidently penetrated the skin. The effect was to cause an inflammation at the spot where the embryos entered,

followed by ankylostoma infection, as shown by the fæces, with the usual symptoms of intense anæmia and extreme debility. Subsequent observation demonstrated the fact that the embryos enter the skin by the hair follicles and push their way towards the hair papillæ, at which spot they pierce the surrounding tissue of the true skin. These views were received with hostile criticism in 1898, but Professor Sandwith, of Cairo, brought the matter up again at the last meeting of the British Medical Association, and remarked on the importance of the discovery in relation to other parasitic diseases. He was supported by Col. Giles, who, however, drew attention to the difficulty of explaining the method of infecting the intestine by embryos introduced through the hair follicles. Dr. Patrick Manson discussed the matter impartially, and suggested as an efficient test that the experiments should be repeated in a country where the chance of previous infection was practically impossible. Dr. Manson's opinion that the embryo sought the hair follicle simply for the purposes of shelter will not, we think, find universal acceptance.

#### Dysentery in Asylums for the Insane.

In a lecture recently delivered by Dr. Washbourn at Guy's Hospital on the subject of dysentery, he referred incidentally to the points of relationship between the dysentery of camps and that which occurs in epidemic form among the insane confined in asylums. This serious matter of dysentery in the asylums for the insane under the London County Council has been most exhaustively dealt with by Drs. Mott and Durham in their report presented to the Asylums Committee. The report shows that there was distinct evidence of spread of infection from bed to bed owing to the dirty habits of the patients, the imperfect arrangements as to personal cleanliness of patients and cleansing and disinfecting of their bedding, and the serious overcrowding of the dormitories. From the description given there can be little doubt that this asylum dysentery is identical with the camp dysentery of the South African campaign; there is the same type of fever and similar symptoms. Moreover, according to Dr. Washbourn, the post-mortem appearances are identical with this exception—that acute cases sometimes die before ulceration has occurred, a condition which he had not observed in South Africa. It has been held that the cases described by Dr. Hale White under the names of simple colitis and ulcerative colitis were really sporadic cases of the dysentery reported on by Drs. Mott and Durham to the Asylums Committee of the London County Council. The conclusions to be drawn seem absolutely clear, that this disease is ascribable to insanitary conditions, that it is infective, and that it can be prevented to a certain extent at the war, and to a very large extent indeed in institutions where we have a right to expect that the greatest care should be exercised to protect the helpless inmates against

infective maladies arising from overcrowding and dirt.

#### Operation under Accidental Hypnosis.

THOUGH operations on patients under hypnotic influence is no new thing, it certainly has not happened to many medical men to repair a vesico-vaginal fistula with the patient under complete anæsthesia obtained accidentally and without premeditation. The facts are given in the *St. Paul Medical Journal* for May, and it is explained that the patient was of a yielding nature, and implicitly obeyed any instructions. The parts in the neighbourhood of the field of operation were infiltrated with a 2 per cent. solution of cocaine, and the woman was told she would have no pain and must keep absolutely quiet. She obeyed so thoroughly that it was quite forgotten for some time that the operation was being conducted without a general anæsthetic. In the course of the proceeding the practitioner had occasion to make some remark to the patient, when it was noticed she made no answer; she was on examination found to be sleeping soundly, with normal colour, pulse, and respiration. On being awakened she complained of feeling sleepy, and sank back into a sound slumber on a few passes being made over her face. She suddenly woke as the last suture was inserted, and left the consulting-room after the operation still complaining of sleepiness.

#### The Forerunners of Tuberculosis in Synovial Sacs.

THE examination of a number of tuberculous joints reveals a considerable thickening of the walls of the vessels of the synovial membranes. This, however, is only apparent, for the thickening is really the result of diapedesis of white cells followed by a deposit of fibres and organisation of connective tissue forming a sheath round the vessel. This sheath encasing the walls of the vessels reduces their elasticity and affords an explanation of the tendency to bleed that characterises tuberculous synovial membranes. Dr. Dieterichs, who describes methods of investigation in *Vratch*, believes that the circulatory disturbance and the formation of the connective tissue sheaths are the forerunners of tuberculosis in these tissues.

#### Dissemination of Disease by the Secretions of the Mouth and Respiratory Tract.

IN the coughing of phthisical patients, even in hospitals where every possible attention is given to hygienic matters—ventilation, light, and the proper disinfection of sputum—we may possibly find an explanation of the fact that patients in the early stages of the disease often do so badly. By an ingenious mask (*New York Medical Journal*, July 27th, 1901) holding a microscopic slide in front of the mouth evidence has been collected to show that the secretions of the mouth and respiratory tract are atomised and given off in the form of a ray in both health and disease. There can

be no objection raised to the conclusion that diseases affecting the mouth and respiratory tract are spread in this manner, as for example diphtheria, scarlet fever, and pertussis. Proof is thus afforded of one means by which clothing on which a patient has coughed may serve to convey disease from house to house, and of the danger of infection to man from the salivary spray of horses, cows, dogs, and cats suffering from certain maladies.

#### Alleged Hospital Neglect.

A CORONER'S jury last week passed a censure upon the authorities of St. Thomas's Hospital. The facts of the case, as disclosed at an inquest in the City of London Court, showed that a woman of 49 was admitted to the hospital after taking a pennyworth of salts of lemon. She was discharged from St. Thomas's a week later, and removed in the custody of the police to the Southwark Police Court, whence she was remanded to Holloway Gaol. On arrival at the prison she was immediately removed to the infirmary, where she died three days later. Medical evidence showed death to be due to acute broncho-pneumonia and Bright's disease. There can be little doubt that most unfortunately the woman was sent from the hospital in an unfit condition. From one report we gather that the patient was discharged by the house physician without a proper physical examination, and that the urine was untested during the whole stay at St. Thomas's. It is to be hoped that the authorities will take steps to prevent the recurrence of such an untoward affair in future. The duties of a house physician are harassing and responsible in the extreme, and it would be preferable to leave the discharge of patients to the care of the police to a medical officer with more leisure and experience at his command.

#### The Toxicity of Camphor.

CAMPHOR is such a popular drug that its comparative toxicity is very apt to be lost sight of. That it is a poison is proved by the death of a child at Huddersfield after swallowing two drachms of camphorated oil, equal to about thirty grains of the drug. Dr. Murrell, in his admirable little work, "What to Do in Cases of Poisoning," states that though camphor often gives rise to alarming symptoms, it rarely proves fatal. The lethal effects are apparently somewhat uncertain, this being due no doubt to its slight solubility, which gives time for the adoption of remedial measures.

#### Testevin's Sign.

THE diagnostic sign which is generally known by the name of Testevin has been lately the subject of patient investigation by Modena, of Pavia, who has lately published the record of his observations. The sign of Testevin is sought for in urine in the following manner:—After removing any albumin, if present, a specimen of the child's urine is slightly acidified, some ether is added, and the mixture well shaken. In a more or less short period of time a small pellet described as having the appearance of collodion is found to float on the

surface of the fluid. It is stated that the substance varies in regard to thickness, consistence, and adhesiveness. It is accepted by many as a characteristic sign of infection during the incubation of acute and chronic infectious diseases, and the more pronounced is this peculiar reaction the greater is supposed to be the severity of the infection. Modena has found it in cases of infectious diseases, but does not consider that it is of any value from the point of view of diagnosis or prognosis.

#### A Mixed Metaphor.

A WRITER in the *Morning Leader* in the course of an eloquent article upon the war, made use of some dental metaphors which show considerable confusion as to the scope and meaning of certain operations connected with dental surgery. "Some day," he says, "we suppose truth will out, but it is a very tedious process, extracted like the filling of a double tooth under the shadow of persistent criticism, and even then one cannot be sure that the whole is in the grip of the pincers." Filling and extraction, it may be pointed out, are two entirely different processes, and both are carried out under the fullest light obtainable. In the writer's mind, however, the dental profession is probably associated with the grip of the forceps to an extent over and above every other aspect of that learned craft.

#### Amyloid Disease in Horses Immunised against Diphtheria.

EXPERIMENTAL study of amyloid degeneration found in horses during the process of immunisation shows a diffuse visceral amyloid degeneration, especially of the liver, with hepatic and intraperitoneal hæmorrhages due to rupture of the liver and fatty degeneration of parenchymatous organs. In the opinion of the investigator, Dr. Zenoni, the horse should be carefully watched for the development of symptoms of amyloid disease, which are shown clinically by exhaustion, want of appetite, loss of flesh, and rapidly increasing anæmia. Unless the injections of toxin are suspended forthwith the animal becomes jaundiced, fever supervenes, prostration becomes marked, and finally collapse is followed by death.

#### Koch versus Alimentary Tuberculosis.

THERE is satisfactory evidence, not only in this but also in most other countries, that the precautions at present in force to prevent the sale of the flesh and milk of tuberculous animals are not to be abandoned in deference to Professor Koch's recent utterances; indeed, the manner in which these views were brought forward has given rise in more than one influential quarter to the expression of very strong opinions. We note with satisfaction that the great dairy companies will continue their efforts to secure the freedom from disease-producing organisms of their milk, and we may take it for granted that local sanitary authorities will not fail to apply the powers vested in them with the same object in view.

### The Sterilisation of Milk.

FEARS have been expressed lest farmers and dairy-men should become careless in view of the facilities for preserving milk afforded by the process of sterilisation. Although this fear is hardly likely to be realised it cannot be too strongly impressed on producers and consumers alike that boiling does not confer upon stale milk the dietetic properties of fresh milk. True it kills all living organisms, but it does not rid the milk of the products of bacterial activity to which many of the ill-effects of stale milk on the young are due. A milk which has been boiled at a stage of bacterial activity is very apt to set up acute gastro-intestinal disturbance, and is from every point of view an undesirable article of food. To be of value the process of sterilisation must be carried out very soon after the milk is withdrawn, and thenceforth special precautions are necessary to prevent its becoming contaminated from the outside.

### The Growth of the Hair in the Insane.

A FRENCH alienist has remarked by a comparison of the growth of the hair in normal and insane women that the growth of the hair is much more pronounced in the latter than in the former, and the phenomenon is specially well marked in the victims of senile dementia and general paralysis. He even goes so far as to regard a profuse growth of hair as an indication of physical degeneration, due, in all probability, to functional disturbance of the thyroid gland or the ovary.

### The Sanitary Institute.

THE next Congress and Exhibition of the Institute will be held in the city of Manchester in the second week of September, 1902, under the presidency of the Right. Hon. the Earl Egerton of Tatton.

THE little town of Raunds, in Northamptonshire, is suffering from a serious outbreak of typhoid fever. The Medical Officer reports that seventy-five cases of typhoid have occurred in a fortnight, most of them being of a very serious character, and traceable to a well supplying 200 families, which had been polluted by storm water.

### PERSONAL.

DR. ROBERT WELSH BRANTHWAITE has been appointed Inspector of State Inebriate Reformatories, a post which is likely to be more or less a sinecure for some years to come, judging from the progress accomplished so far in providing these much-needed retreats.

DR. EDMUND GWYNN has been presented with a pair of silver candelabra and a silver bowl by the medical practitioners of Hampstead, on the occasion of his retirement from the post of Medical Officership of Health. The presentation was made by Dr. Ford Anderson. Dr. Gwynn was also presented with a set of four silver bowls by Professor Stokes on behalf of his colleagues on the Hampstead Borough Council.

DR. WILLIAM HANNA, M.A., M.B., B.U.I., D.P.H.

Camb., was elected Assistant Medical Officer to the Port of Liverpool on the 1st inst. by the port sanitary authority. Dr. Hanna studied at Glasgow, Cambridge, and Berlin. These studies were supplemented by an experience of three years on plague duty in India, and in the investigation of tropical diseases at the Government Research Laboratory, Bombay.

DR. W. TAYLOR, Chief of the Army Medical Department in India, who has now been appointed to the headquarters of the Royal Army Medical Department in London, will not take over the duties for some six weeks. Surgeon-General Taylor, directly he joins the Headquarters Staff at Victoria Street, will be chiefly engaged in carrying out the further reorganisation of the R.A.M.C.

A GREAT ovation was accorded on Friday night at Manchester, when thirty men of the Manchester Volunteer Medical Staff Corps returned to the city from the seat of war in South Africa, after an absence of twenty months. The crowd was so great and the enthusiasm so demonstrative that they had the greatest difficulty in reaching headquarters, where the officer commanding the corps (Surgeon-Colonel Coates) subsequently addressed a few words of welcome to them.

DR. PAUL GAERNAULT, of Paris, has suddenly leapt into world-wide fame by his offer to test upon himself Dr. Koch's theory of the non-transmission of bovine tuberculosis to human beings. He has written to the German Professor offering to undergo inoculation with bovine tuberculous material. Dr. Garnault states that he is forty-one years of age, that he weighs over 100 kilograms, that his height is 1.81 metres, that his health is perfect, and that he has no children.

## Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

### THE DIFFICULTY OF DIAGNOSIS IN INFECTIOUS DISEASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—The highly speculative conditions to which medical men are exposed in the diagnosis of disease subject to notification, and the responsibility, both moral and legal, thereby incurred, render the question of more or less considerable moment. The difficulty is no doubt intensified among those practitioners whose lot has cast them among a nest of the less opulent classes whose circumstances are such that nothing save dire necessity or anxiety prompts them to seek medical advice until the appearances may seem to them to indicate gravity. Hence in many of these cases the landmarks to diagnosis in any rash, &c., which may or may not have appeared, have become effaced, and the practitioner is often driven to the wildest conjecture as to the original nature of the disease. Taking the law, however, as we find it there can be no doubt as to the advisability of granting considerable latitude towards medical practitioners in their discretionary ability and onerous duties with regard to notification. I have heard it stated, and this on authority too, that medical men in the present day notify rashly, and the officials, therefore, should act with extreme caution before applying any oppressive measures in attempting to uphold the law in the event of any supposed breach, otherwise the procedure would

tend to stimulate timid members of the profession to carry on notification to an extreme degree which, as I have just stated, has already been suggested on authority.

Returning to the point concerning the difficulty of notification I may mention a few cases within my own knowledge. On one occasion a domestic servant whom I attended came to the house on the day following, and appeared to be suffering from chicken-pox. Although the case as I thought was anything but typical, nevertheless it flashed across me that it might be one of small-pox, however, there happened to be little or no constitutional disturbance, and as there was a fair sprinkling of rash on the face I concluded that the general state of health was inconsistent with an attack of small-pox seeing there was, as I have said, some amount of rash. The maid, however, was sent home and a local practitioner called in, as also another, presumably in consultation, both of whom notified the disease as small-pox. Feeling reasonably certain that a mistake had been made, I called on the medical officer of health and likewise at the ambulance station, and through the courtesy of the official at the latter department, I was informed by letter that the case had been returned in a few days chicken-pox.

On another occasion quite recently I was fetched to see a child suffering from throat affection, and as there appeared some herpetic eruption on the lips I believed the case to be catarrhal, and calling the following day thought the same. On the third day, however, I was surprised to find the child at play in the garden, and on examining the throat on this occasion a tough-looking piece of membrane appeared on the tonsil, which I concluded was diphtheria, and explained the necessity of notification, but the husband not being at home I suggested for satisfaction calling in another local medical man; whereupon the mother remarked to me in a confidential tone that her husband was "a funny man," after which she went on to explain that the husband had actually taken the child to the surgery of another practitioner during my attendance, and that he pronounced it cold, probably from the same reason as I, viz., the herpetic eruption. As, however, opinion was set against opinion, I suggested striking the balance by calling in another, but on the arrival of the husband home the same medical man was consulted, and on this occasion he notified diphtheria. A point of interest seems to me to consist in this, viz., that supposing the medical man in question had had no opportunity of seeing the case the second time a *prima facie* suspicion of non-notification might present itself, and indeed a prosecution took place, and was referred to in your columns, in one point analogous to this, inasmuch that in both they were taken for examination to a surgery.

On yet another occasion, and this recently too, a child was brought to me apparently suffering from scarlet fever—at least the rash was identical—sore throat, and the faintest, if any, catarrhal symptoms, but fortunately notification was delayed, and in three days' time it turned out an unmistakable case of measles.

I have mentioned these instances merely to illustrate the difficulties involved in notification, difficulties, too, which may not be so readily appreciated by those in high places. How far notification may have decreased mortality, or to what extent isolation has reduced the number of infectious diseases, is a problem perhaps not easily solved, as the evidence is complex, but with regard to isolation it would appear that if any disease of an infectious type invade a house, in the majority of cases other members of the household seem to contract it.

Every medical man in a populated district must be aware of the fact how frequently infectious diseases are brought to the house, and we may thereby infer that if notification and isolation are what they purport to be or anticipate, and of the importance that they appear to merit, the sooner the system of allowing druggists to prescribe be stopped the better for the public interest, otherwise the effects of the Act must, to a greater or less degree, be nullified, because we may be certain that a percentage of mild infectious cases escape detection

through falling within the meshes of their nets and due to their direct or indirect prescribing.

I am, Sir, yours truly,

CLEMENT H. SEES, M.B.C.S., L.B.C.P. Edin.

P.S.—I must mention that in the case of diphtheria referred to above other members of the household were notified, and an infant died, but not under my care.

"LATENT CERVICAL FRACTURE"

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you please say for the satisfaction of your readers, How could force sufficient to break the transverse process of the fourth cervical vertebra be applied so as to leave no external mark?

Could such a fracture result from muscular force?

What is Simon's definition of a "latent" fracture?

How many such fractures are on record?

I am, Sir, yours truly,

CLEOFAS.

[From the published report of the post-mortem examination evidence of subcutaneous extravasation of blood led to the examination of the posterior cervical region. A fracture of a transverse process of the fourth cervical vertebra is not likely to result from muscular action. Lidell's definition is as follows:—"In the examples of so-called latent fracture of the vertebræ the spinal cord is not at all affected by concussion, nor by contusion, nor is it compressed by displaced bone, nor by extravasated blood." We have not Simon's definition before us. To ascertain the number of recorded "latent" fractures of the spine would involve a tedious and laborious investigation.—Ed.]

THE PROPOSED BRITISH AND COLONIAL JOURNAL OF OBSTETRICS AND GYNÆCOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a somewhat lengthy letter, Dr. Sinclair seems to me to miss the one point which was necessary. There is undoubtedly a feeling that the British Gynæcological Society has been thrown over in favour of the Obstetrical Society, and I would suggest that Dr. Sinclair should let us know how many Fellows of the Gynæcological and how many of the Obstetrical Society were invited to the preliminary meeting, noting at the same time how many Fellows of each society asked practice in London. By doing this Dr. Sinclair will at once show how things stand, and if he does not do it, I, for one, will draw my own conclusions.

In a letter of three lines Dr. Sinclair can settle the relation of the proposed journal to the two societies.

I am, Sir, yours truly,

SKENE KEITH.

London, August 20th, 1901.

MR. PEREGRINE PURVIS has sent a donation of £1,000 to the Royal Free Hospital, London.

MESSES. T. B. SHAW, M.B., P. T. Nicholls, A. T. Gailton, M.B., and G. S. Davidge have been gazetted surgeons to his Majesty's fleet, with seniority, of August 10th.

Royal Army Medical Corps.

SURGEON-CAPT. C. DALTON, embarked at Liverpool on Saturday last for Sierra Leone. A draft of 100 men embarked at Southampton on the 19th inst., on the s.s. *Canada*, for South Africa. Surgeon-Major G. Tuke joined at Woolwich on the 10th inst. Lieut. Davies and Lieut. A. W. Gibson have been posted to the Cambridge Hospital at Aldershot for duty. Surgeon-Major Dodd has assumed temporary charge of the Connaught Hospital at Aldershot during the absence of Lieut.-Col Wilson.

## Literature.

### SENN'S "PATHOLOGY AND SURGICAL TREATMENT OF TUMOURS." (a)

THE second edition of Professor Senn's book on "The Pathology and Surgical Treatment of Tumours" forms a substantial volume. The illustrations are very numerous and, on the whole, well selected. Many of those representing histological details are excellent. A very liberal use has been made of italics in emphasising important points in treatment and in the definition of terms. The successful surgical treatment of tumours depends, probably more than other branches of operative surgery, on the resourcefulness of the surgeon rather than on the remembrance of any formulated rules. In the book before us the operations described are those which have been found most generally useful, or which serve to illustrate some great principle in operative surgery. The general medical reader is not confused by an exhaustive descriptive list of operations.

The direction is given in italics on page 408 that "the removal of a subcutaneous lipoma must be done under strict aseptic precautions," and special reasons for this are then given. The inference is only too likely to be drawn from such statements that in operations on other forms of tumour in which these special anatomical conditions are not present strict asepsis is not necessary or essential. Practice based on such a belief must result, sooner or later, in what would be considered lamentable results.

Multiple false neuromata and molluscum fibrosum are regarded as synonymous terms. Even allowing that molluscum fibrosum be connected with, or even directly the result of changes in the nerves of the skin—and this seems to be as yet non-proven, it is almost indispensable for the clear understanding of their clinical features that the two conditions should be distinctly marked off from one another. It will be pretty generally conceded that *clinically* the two conditions are distinct, consequently it seems undesirable to place them so closely together as Professor Senn does. We have noticed confusion in other American textbooks in the descriptions of false neuromata and molluscum fibrosum. The terms macroglossia and macrocheilia are restricted to lymphangioma of the tongue and lips. It is well to thus limit the applicability of these otherwise indefinite terms.

### OPPENHEIM'S NERVOUS SYSTEM. (b)

WE have here not a first appearance, but a well-known and well-established work, now in its second edition, of which it may be well to give some fuller detail than usual of the scope, purpose, and style. The author's main idea is to block it at the outset into two main parts, viz., the general part and the special part. In the general part, of course, the subject is opened up in general terms, the reader is led through the simpler and broader pathways of knowledge of the subject as they first present themselves, and from the point of view of height and breadth has the general differentiation of the great nervous system at an advantage. Methods and modes of examination may be said to comprise the first part of the work, and here undoubtedly there is more to be said than appears on the surface. The author lays stress on the importance of methodical detail, in the methods of examination, of the beginner; but he does not think the experienced examiner requires a fixed order of examination. We join issue here, for the success of our young physicians is due to the fact that they are still methodical, and the failure of older men, who now lag in the paths of research, is due to the fact that "the gold coast" is too attractive, and time to a busy consultant means money. Of course, we make exceptions to this statement. We agree with the author that the question of heredity should find a

first and important place; but sometimes this takes up a long time, and the consultant trusts to his experience to pass it by. We believe this is a great mistake. The author is rather hurried in dealing with the anamnesis, and he sums up the most important inherited diseases without any discrimination. A thorough and sound descriptive article on the evolution of the neurons would be most instructive and valuable, and full of suggestion for practical uses. It is not enough to tell us that "morbid inclinations to suicide, alcoholism, &c., indicate a neuropathic diathesis." There is too much begging of the question here. Again, much more might be said of the diseases which predispose to nervous affections, and certainly the statement regarding consanguineous marriages is a very meagre one. It requires a chapter to itself. It is not usual for writers on diseases of the nervous system to insist that a knowledge of psychiatry must always accompany, if not precede, that of neurology. In this country such a statement is usually conspicuous by its absence. It is, nevertheless, a sound expression of opinion, and applies to the whole gamut of disease as well. The author goes very fully into the question of the stigmata of degeneration, the skull, ear, teeth, palate, &c., but very wisely makes this reservation, that "too much importance should not, however, be given them, as almost all may occur in perfectly normal individuals." The general symptomatology of the muscular system receives a very considerable share of attention, but more explanatory references are needed. The minute muscular system of face, eyes, tongue, larynx, &c., is here fully treated of. We come now to the second or special part, which is mainly taken up with spinal, brain, and peripheral diseases, and practically occupies the chief portion of the book. The anatomical description, especially microscopic, of the spinal cord, is very good, and, of course, much of it is repetition; but that is unavoidable. What the student and practitioner will most appreciate is the fresh light which is thrown upon function, especially the reflexes. Beginning with the system diseases of the spinal cord, we find locomotor ataxia heads the list. We find also here, as elsewhere, that the author is by no means redundant in his descriptions, and that little space covers a good deal of matter. On the subject of treatment Oppenheim is more communicative than some others. He evidently has something to say worth taking note of, and he is evidently more hopeful of results in the early treatment of this wretched disease. Into descriptions of neuritis and multiple neuritis the author enters with much detail and discrimination, but on the subject of craft paralysis we think he might have said more. On introducing the section of diseases of the brain, a brief anatomical description is given. A brief, but fairly satisfactory, reference is made of the localisation of function, but though with some slight equipment to introduce the clinical description the reader is referred to other and fuller details, so as not to over-write this book. The general phenomena of cerebral disease are here classed under two heads (a) those representing organic disease, (b) those representing functional disease. Into these, here and elsewhere, the author enters with great care, and this part of the work will be found most interesting and practical. The method adopted here is very good. Under the title of local symptoms, Oppenheim treats first of symptoms of irritation, beginning with the cortical motor zone, and treating of localised spasms, including Jacksonian epilepsy. From symptoms of irritation he passes on to paralysis, but here, though he is on practically the same ground, the author is not explicit, and does not distinguish plainly. Space forbids us to linger here longer, but we commend all this to the reader, especially the section on speech defects, which is not too long. A long series of excellent chapters appear on the diseases of the meninges, the brain substance, &c., and here, as elsewhere, it might be expected that more might be written. The well-read and experienced student and practitioner, however, will read and know between the lines much more than appears on the surface. He will find here much valuable help, especially

(a) "The Pathology and Surgical Treatment of Tumours." By W. Senn, M.D., Ph.D., LL.D., Professor of Surgery, Chicago Polyclinic, Rush Medical College, &c. Second Edition, Revised. 8vo. Pp. 718. Illustrated by 478 engravings and 12 full-page plates in colours. Philadelphia: W. B. Saunders, 1900.

(b) "Diseases of the Nervous System." By H. Oppenheim, M.D. Philadelphia and London: J. P. Lippincott and Co.

in the differential diagnosis of many difficult and obscure brain diseases. Coming near a close the author in Section IV. takes up the neuroses. A brief introduction on the term Neuroses would have been useful. The term is much read; its definition is not clear, nor are its limits well understood. Here he plunges right away into hysteria. Why? We know not; but we do know that we heard of hysteria long before we ever heard of "The Neuroses." We are not even clear yet as to how much of so-called hysteria is neurosis, and how much is not. As regards the proportion of women and men relatively affected, we agree with the author that the figures of Briquet must be modified. This section from its Continental origin is sure to have something new for many of our readers, and we would specially direct attention to hypnotism, neurasthenia, phobias, &c. The remaining sections, dealing with diseases of the sympathetic nervous system, angioneuroses and euphorooses, and with neuro-toxæmias are very important, but rather short. The illustrations are very appropriate, and altogether the work is well worthy of a place in English medical literature.

LEFTWICH'S INDEX OF SYMPTOMS. (a)

THE idea underlying this little work is ingenious, and we may infer from the fact that it has reached a second edition that the author's scheme has met with a favourable reception. The contents are divided into the main chapters, one of symptoms ascertained by interrogation and another of symptoms discoverable by physical examination. The method is the same throughout; under the head of a particular symptom is given a list of the various conditions or diseases to one or other of which it may be due. In practice this leads to some rather startling *rapprochements*. For instance, under "sleeplessness" we get as possible causes collapse of lungs and trichinosis, while under "night terrors" we have mucous disease (?) and frights. Some of the references excite surprise, for example, "bulimia" is associated with exophthalmic goitre, iodism, and whooping-cough, while anorexia is described as possibly due to cancer of liver or stomach, cystitis, empyema, &c. Really we fail to see what possible assistance such references can afford in arriving at a diagnosis. Of course all the lists are not equally wide of the mark, and herein lies the value of the work. The more special the symptom the greater the value of the list which it precedes. The book concludes with a useful little chapter on methods of diagnosis for the use of clinical clerks, &c. and it is illustrated by seven figures. We can quite believe that the work has entailed upon the author a large amount of patient work, we only fear that the result may not be found commensurate with the labour and energy devoted to it.

GOODSALL'S ANUS AND RECTUM. (b)

THIS book commences with an excellent chapter, fully illustrated, on the anatomy of the parts; the second chapter is on general diagnosis, and gives some very practical suggestions for questioning and also for examining the patient. The chapter on abscess comes next, and opens the way for the one on ano-rectal fistula, which is not only profusely illustrated but constitutes in itself an exhaustive treatise on the subject, occupying 81 pp. Recto-urethral, recto-vesical, and recto-vaginal fistulae are more lightly dealt with, but sinus over the sacrum, a condition the literature on which, the authors point out, is very limited, is more fully entered into, some illustrative and illustrated cases being given which much enhance the authors' explanation. The description, position, aetiology, symptoms, diagnosis, and treatment of anal fissure is next given, together with a graphic account of the two principal operations for its relief. The last chapter is devoted to

external and internal piles. With regard to the latter the authors have a very strong preference for ligature (Salmon's operations), and give their reasons for objecting to the other seven methods of operation. Altogether this first volume, though containing nothing particularly new, is well worthy of perusal, if only for the very graphic illustrations, and we look forward with pleasure to the advent of Part II.

GANT'S MOCK-NURSES. (a)

THE second edition of Mr. Gant's book is supplemented by an interesting auto-memoir of the author, which takes the reader back to the beginning of last century, with reminiscences of Eastbourne, Hastings, and St. Leonards, then merely villages, next on to the Crimean War, with glimpses of Balaclava, Inkerman, Scutari, &c., culled from Mr. Gant's experiences when acting as one of the civil surgeons to the troops, and finally to the author's long connection with the Royal Free Hospital and the evolution of that institution into the practical medical school for women. A review of the first part of the book has already appeared in our columns.

BICHAT'S GENERAL ANATOMY. (b)

THIS is the first fasciculus of the re-edition of Bichat's work—a work of positive philosophy—and conforms to the spelling, punctuation, &c., of the 1801 edition. The plan of the work is to consider by itself each of the single systems which by their different combinations form the human organism; the base of this plan is anatomical, but the details it embraces belong also to medicine and physiology. The several doctrines put forward are opposed to those of Boerhaave, and differ from those of Stahl and his followers. After some general considerations the author deals with the cellular system, with the nervous system, and with the vascular system, all of the subjects being treated in a philosophical manner and the whole fasciculus is interesting as an abstruse study.

MANSELL MOULLIN'S WHEN TO OPERATE IN INFLAMMATION OF THE APPENDIX. (c)

THESE four lectures, which were originally published in, and reprinted from, the *Clinical Journal*, and which have been revised and partially rewritten for the present edition, can be read with advantage by every medical man. Mr. Mansell Moullin is evidently an advocate for operation in nearly all cases of inflammation of the appendix, and his reasons are so straightforward and his arguments so convincing that his words should go a long way towards converting those who are more in favour of expectant treatment.

HALLS' DISEASES OF THE NOSE AND THROAT. (d)

WE have read this book with great pleasure. The style is clear and concise, and the descriptions are graphic. The information is up-to-date; the volume contains more than enough for general practitioners familiar with the use of the laryngoscope; and it may be described as an excellent text-book for students beginning the study of the subject.

We heartily endorse the condemnation of the removal of the inferior turbinated bone by the spokeshave; an operation of which we were among the first to disapprove, as likely to be followed by troubles worse and less easily treated than the condition for which it was proposed,

(b) "Diseases of the Anus and Rectum." By D. H. Goodsall, F.R.C.S., and W. Ernest Miles, F.R.C.S. (in Two Parts). Part I. Pp. 51L. London: Longmans, Green, and Co.

not to speak of the danger from hæmorrhage during and immediately after its performance.

We are glad to see that the "head down" position for removal of adenoids is here advocated. So far as we are aware, all the deaths from this operation have occurred during its performance with the patient in the upright position, either from syncope, from chloroform, or from drowning by blood. These dangers are obviated, or reduced to a minimum, by the "head down" position, and we have no doubt that this method will beat the older one out of the field.

There is little in the work for adverse criticism. The statement at p. 142, that "the sense of smell is at least twice as acute in man as in woman," does not accord with our experience.

#### THE THERMAL WATERS OF BATH. (a)

THIS small book not only gives an account of Bath and the development of its now splendid bathing establishments, but also gives much information on the use of massage, with or without the waters, that will be found very useful by a large class of invalids. The author claims, and we think quite correctly, that the Bath waters, aided by judicious massage, can do quite as much good in cases of dilated heart as can be accomplished by the Naheim treatment. The observations, at page 29, on this subject are well worth study.

In his concluding chapters the author does not shirk statistics. In rheumatoid arthritis he gives 5 per cent. as cured and 80·7 relieved. No one knowing anything of the complaint will think such results unfavourable. Of cases of true gout treated 13·9 were cured and 80·7 relieved.

The appendix which closes the book affords information as to charges and fees for the baths. Though small and of very moderate cost the book is very full of interest and instruction, and everyone contemplating a visit to Bath will do well to get a copy, and will find the perusal well repay him.

#### TUBBY'S INTRA-ABDOMINAL SUPPURATION. (b)

THIS little book comprises seven clinical lectures delivered at the Westminster Hospital, of which four are devoted to Appendicitis, one to Sub-diaphragmatic Abscess, one to Pelvic Suppuration and Tuberculous Peritonitis, and one to General Peritonitis. The four lectures on Appendicitis are very practical. They include: Anatomy, Pathology, Bacteriology, Ætiology, Symptoms, Signs, Complications, Sequelæ, Diagnosis, Prognosis, Treatment, and should prove especially useful to students who eventually take a country practice. The next lecture on Sub-diaphragmatic Abscess is well worthy of perusal, the symptoms and signs being very clearly given, particularly those in connection with an abscess of this kind caused by perforation of the stomach. The last two lectures are fully up to the mark of the first five, and Mr. Tubby is to be congratulated on having placed before the profession in book form so much instructive matter.

#### ALLCHIN'S MEDICINE.—PART II. (c)

PART II. of this important manual sustains the opinion expressed on the appearance of the first part, namely, that it contains a large amount of valuable work. It continues the description of the general diseases, and includes those caused by parasites, by poisons introduced into the body, primary perversions of general nutrition and diseases of the blood. Under "Opium" washing out the stomach is advised only when the dose has been taken into that organ. Surely, it is nowadays recognised that morphia, if in-

jected hypodermically, is rapidly excreted by the stomach. In directing that the patient should be kept walking to and fro, it would be well to point out that this plan of treatment has not unfrequently killed the patient by sheer exhaustion. The danger of relapse in these cases is very properly insisted upon, but no mention is made of the necessity of emptying the bladder by means of a catheter. On p. 66 we notice "morphia" and "morphine" on the same page. Under phosphorus we find no mention of Stockman's classical work on "phossy jaw." It is correctly stated that codeia has no advantage over morphia in the treatment of diabetes mellitus, but it might be added that codeia has the great disadvantage, especially in hospital practice, of costing more than twice as much as morphia. Most of the articles contain good matter well arranged, although at times the information is of a somewhat elementary nature. So far as our criticisms are concerned they mainly deal with minor points of omission. For instance, no mention is made of the value either of belladonna or ergot in diabetes mellitus. Under hæmophilia it is surprising to note that a systematic manual of this importance does not mention the name of Dr. Wickham Legg, in spite of the fact that his treatise on the malady published in 1872 was regarded as the standard work on the subject. Even as recently as 1898 he contributed an article on the subject to Clifford Allbutt's *System of Medicine*. The articles on diseases of the blood have been entrusted to a writer who is now a Commissioner of Lunacy. The subject, however, has been ably dealt with, and is illustrated with some extremely beautiful coloured plates, and we are glad to note that the writer does not think it necessary to call a red corpuscle an erythrocyte. No mention is made of the Tallerman superheated air treatment in the otherwise extremely able article upon gout. Under rheumatoid arthritis the topical application of dry air heated to 250° F. or 300° F. is mentioned only to be dismissed curtly by Dr. Dawson with the remark that it is doubtful if it has any curative action. Dr. Allchin, who writes the article on chronic rheumatism, says that dry heat will "sometimes effect most satisfactory results." It seems almost incredible that such an attitude should be taken in a modern manual of medicine with regard to so powerful a therapeutic agency in gouty, rheumatic, and allied conditions as that afforded by the Tallerman superheated air-treatment. On the whole the editor's laborious and responsible task has been well and conscientiously performed. Both he and the publishers may be congratulated upon the general excellence of their production, which should be in the hands of all practising physicians.

#### HUNTER'S ORAL SEPSIS. (a)

THIS is the reprint of an article which appeared in *The Practitioner* of December, 1900, and is published in this separate form "in the hope that it may serve to draw additional attention to a source of disease extremely prevalent and most egregiously overlooked."

In the first place attention is directed to the local effects of oral sepsis as affecting the mouth, jaws, tonsils, and pharynx; and then Dr. Hunter points out that infective disease of the mouth is not the "mere question of the presence of an organism, however pathogenic, but a question of dose and resistance." This is the keynote of the book. According to the bacteriological investigations of Miller, Galippe, and Vignal, Jung, and more recently Professor Arkov of Budapest, it is shown that the bacillus gangrenæ pulpæ was present in 95·3 per cent. of cases of dental caries; the staphylococcus pyogenes aureus in 34·8 per cent., and the streptococcus pyogenes in 23·2 per cent., &c., &c.

Now, without doubt, as Dr. Hunter points out, if such pus organisms are constantly being swallowed there must result what he terms a septic gastritis. And this in addition to the indigestion set up by the swallowing of imperfectly masticated food (owing to the bad teeth).

(a) "The Thermal Waters of Bath." By Gilbert A. Bannatyne, M.D., M.R.C.P., Honorary Physician to the Royal Mineral Water Hospital, Bath. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd.

(b) "Clinical Lectures on the Various Forms of Intra-Abdominal Suppuration." By A. H. Tubby, F.R.C.S. Pp. 91. Medical Publishing Company, Limited.

(c) "A Manual of Medicine." By W. Allchin, M.D. Lond., F.R.C.P., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital, &c., &c. Part II. London: Macmillan and Co. 1900. Price 7s. 6d.

(a) "Oral Sepsis as a Cause of Disease." By William Hunter, M.D., F.R.C.P. London, Paris, New York, and Melbourne: Cassell and Company, Limited. 1901. Pp. iv. and 30.

Particulars are given of six cases, all suffering from three main symptoms, viz., salivation, gastric discomfort, gastric catarrh, all of which were cured when either the ill-fitting septic plates were regularly and properly cleaned or perhaps a few old stumps removed.

Regarding the more general effects— toxic effects—of oral sepsis Dr. Hunter tabulates five varieties, viz., fever, septic rashes, purpuric hæmorrhages and bleeding from the gums, profound septicæmia, and toxic neuritis.

Though Dr. Hunter brings forward some seven cases in support of his view that such conditions, as are mentioned above, result from the constant swallowing of pus organisms due to oral sepsis, still the present reviewer would advance the opinion that a much larger number of cases must pass under observation before oral sepsis is shown to be the definite and absolute cause of such conditions. Undoubtedly, Dr. Hunter has done well in putting prominently before the busy general practitioner a possible cause of many obscure gastric disturbances, which is as easily observed as it is generally overlooked.

To the dental profession the book should be of great interest and sound a loud note of warning. For, as Dr. Hunter points out, patients suffering from oral sepsis, who visit their dentist on the urgent entreaties of their physician, often are sent back to the latter in as bad a state as when they went away.

### Obituary.

#### SURGEON-GENERAL CHARLES RICHARD FRANCIS.

WE regret to have to announce the death of an old friend of the MEDICAL PRESS AND CIRCULAR in the person of Surgeon-General Charles Richard Francis, of the Indian Army (retired), who died at his residence, 41, Spencer Park, S.W., in his eighty-first year. Between 1844 and 1875 the deceased officer filled numerous civil and military appointments in India, having at one time occupied the position of Principal and Professor of Medicine at the Medical College at Calcutta, and Physician to the College Hospital. He was also Examiner in Medicine and Obstetrics to the University of Calcutta. Towards the close of his Indian career he held successively the posts of Secretary to the Surgeon-General, Deputy Surgeon-General, and officiating Surgeon-General with the Government of India. In 1853 he was appointed by the Government to investigate, in conjunction with Dr. Frank Pearson, the nature of the mahamurree, which was raging as an epidemic in the hill districts of Kumaon and Gorkhwal. Drs. Francis and Pearson succeeded in demonstrating the identity of this disease with "bubonic plague," and their investigations proved the basis of a valuable report thereon. Dr. Francis devoted much time and energy to the study of snake and snake poison, with the view of discovering an antidote. He was a prolific writer, and was at one time editor of the *Indian Medical Gazette*.

### Medical News.

#### Prosecution of a Medical Man under the Sale of Food and Drugs Acts.

In the Dublin Police Court, on August 9th, before Mr. Wall, K.C.; Mr. J. C. McWalter, L.R.C.S.I., M.P.S.I., trading as J. Leonard and Co., pharmacists, was summoned under the Sale of Food and Drugs Acts for having, on June 28th last, sold to Inspector Rowsome, a Corporation official, a quantity of spirit of nitrous ether which was not of the nature, substance, and quality of the article demanded. The quantity purchased was six ounces. Sir Charles Cameron, City Chemist, certified that the article contained only 0.4 per cent. of ethyl nitrite, whereas it should have contained at least 1.75 per cent. Mr. A. F. Blood, K.C., appeared for the defence. Inspector Rowsome proved the pur-

chase of the drug, and Sir Charles Cameron's certificate was submitted. Mr. Blood drew attention to the fact that in the bottle in which the Corporation specimen of the drug was contained there was only a small quantity of the liquid left, and he submitted that so small a quantity could not be analysed as required by the Act of Parliament. Any deterioration which had taken place occurred after the drug left defendant's branch establishment at Great Britain Street, where it had been procured. Dr. Ashe deposed that the compound in question was of a very unstable nature, and should be secured in a coloured and stoppered bottle. It was really a gas dissolved in spirit, and the bottle in which the specimen now was contained was a most improper receptacle therefor. The magistrate was understood to say that anyone who had to do with whisky knew the importance of keeping it in stoppered bottles. The connection was not apparent, but the several scientific experts present assented to the proposition. Professor C. R. C. Tichborne, M.P.S.I., gave evidence that the spirit of nitrous ether was very volatile and was extremely subject to the action of light and air. He did not consider that the sample produced was in a proper bottle. It was agreed eventually that the liquid in the bottle should be sent to Somerset House for analysis, and the case was adjourned pending the result.

#### Harmful Headache Powders.

AT the Ulverston County Court on Aug. 18th, Jeannie and Willis Shillitoe sued W. B. Hird, a grocer, for £50 damages for a fortnight's illness suffered by the female plaintiff after taking one of Proctor's headache powders sold by the defendant. The medical evidence was very conflicting. One medical man stated that the powders contained 6½ to 7½ grains of antipyrine, and the British Pharmacopœia prescribed the ordinary dose as from 1 to 3 grains. On the other hand, Dr. Anderson asserted that in most headache cases a dose of 4 to 14 grains could be given safely. His Honour held that the negligent sale of a drug had been proved, and gave judgment for plaintiffs for £21.

#### The Manchester Medical Guild.

THE following resolutions were unanimously passed at the last meeting of the Medical Guild, Manchester, on July 26th, as follows:— 1. That in the opinion of the Medical Guild, seeing that vaccination is made compulsory in the interest of public health, the parent or guardian of a child should have the right to select any registered medical practitioner, who is willing to do so, to perform the vaccination, and that the cost of the same should be defrayed by the State at a fixed rate. 2. That, in the event of the foregoing resolution being passed, the Council be requested to consider what steps can be taken to influence future legislation on the subject.

### Pass Lists.

#### Army Medical School, Netley.

SURGEONS on probation successful at both the London and Netley Examinations. Prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions are determined by the marks gained in London added to those gained at Netley, and the combined numbers are shown:—

F. W. Lambelle ...	5,289	M. C. Beatty ...	3,947
L. J. S. Cahill ...	4,703	J. R. Welland ...	3,686
W. C. Stevenson* ...	4,165	H. W. Long ...	3,385

\* Gained De Chaumont Prize in Hygiene.

List of surgeons on probation recommended for commissions in the Royal Army Medical Corps at the close of the 82nd session. These gentlemen were nominated to the Army Medical School:—

T. F. Ritchie ...	2,105	H. Rogers ...	1,688
A. W. Sampey ...	1,786	W. J. S. Harvey ...	1,606
T. J. Potter ...	1,778	W. Davis ...	1,570
A. J. Williamson ...	1,751	J. C. Hastings ...	1,426
E. V. Ayles ...	1,681	D. O'Donoghue ...	1,399

## Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULARS, may now be had at the office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

VICTOR.—The quotation is from Addison, and runs as follows:—"A wealthy physician who can help a poor man and will not without a fee has a less sense of humanity than a poor man who kills a rich man to supply his necessities."

R.A.M.C.—The time is past, let us hope, when an Army medical officer is "to be seen and not heard." We shall be very pleased to consider any carefully thought out suggestions on the reform of the Service, although frankly it appears to us that the subject has been well threshed out already.

M. E.—If the skiagram was made at your request, and paid for by you, the copyright, we imagine, is yours. In any event it would be a gross breach of commercial etiquette for the operator to make public use thereof without previously obtaining your consent.

J. H. C. (Salford).—Many thanks for letter. We should like to see the matter taken up as you suggest, and we think the case merits the attention of the Irish Medical Association.

Dr. H. S. C.—The decision of the arbitrator has only just been given. It is in effect that the past arrangement between the County Council and the borough for providing accommodation for pauper lunatics should cease, and that a new arrangement be made under section 244 of the Lunacy Act, 1890.

Dr. J. E. W. (Vienna).—The gentleman addressed is away on holiday, but returns this week, when your communication will receive attention.

Dr. J. C. T.—Communication is marked for next number; proof will be sent you in due course.

### JURYMEN AND MURDERS.

D.C.L. (Brighton).—1. The number of jurymen at a coroner's inquest may be anything between twelve and twenty-three. Anyone should necessarily arise, may be summoned from the street to act as jurymen. 2. Yes. The late Dr. Bond was engaged professionally for many years in nearly all the great murder trials. He owed his first appearance in criminal work to his post as Surgeon to the Detective Department of the Metropolitan Police. His first notable achievement was the discovery in the brain of the woman murdered by Wainwright of three bullets that had been overlooked in a previous post-mortem. Among other medico-legal cases he was prominently engaged in the Camp murder, the mysterious Jack the Ripper murders, and also the Lefroy, Lamson, and Neil Cream cases. His uncle acted as a surgeon to the London, Brighton, and South Coast Railway, and under him Dr. Bond is said to have acquired his first experiences of surgery by attending a railway accident at Bishopstoke.

F. G. WILLIAMSON (Cumberland).—We have ascertained that the writer of the medical notes to correspondents in the Sunday newspaper you mention is a qualified medical man, but the only body likely to take up the matter is the Medical Defence Union. The General Medical Council would, probably, take no cognisance of an offence of this kind unless formally brought to its notice.

### Appointments.

ARTHUR, RICHARD, M.D. Edin., Honorary Assistant Surgeon, to the Ear and Throat Department of the Sydney Hospital.  
BARNES, E. W., L.K.Q.C.P.Irel., L.F.P.S.Glasg., District Medical Officer to the Liverpool Union, vice Dr. Caldwell, resigned.  
COLLUM, ROWLAND W., M.R.C.S., L.B.C.P., Assistant Anaesthetist to the Hospital for Sick Children, Great Ormond Street, W.C.  
COULTER, B. J., M.B., F.R.C.S.Irel., Ophthalmic Surgeon to the Newport and Monmouthshire Hospital, vice B. W. Gowring, M.D., resigned.  
CURTIS, H. J., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Royal Hospital for Children and Women, Waterloo Bridge Road.  
DIX, E. H., M.B., B.S.Durh., Junior House Physician to the Royal Infirmary, Newcastle-on-Tyne.  
GRESSWELL, D. A., M.D.Oxon., Permanent Head of the Department of Public Health, Victoria.  
HESLOP, J. W., M.B., B.S.Durh., House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

ORMEROD, HENRY LAWRENCE, M.D., B.Ch. R.U.I., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Shirehampton Isolation Hospital.  
PORTER, A. E., M.D., D.P.H.Cantab., Assistant Medical Officer of Health for the City of Leeds.  
ROE, B. W. E., L.R.C.P., L.R.C.S.Irel., Medical Officer for No. 2 District of the Ongar Union.

### Vacancies.

Belmullet Union.—Medical Officer. Salary £130 per annum, and £10 per year as Medical Officer of Health, together with registration and vaccination fees. Immediate application, accompanied by diplomas and testimonials, to E. N. Flynn, Clerk of Union. (See Advt.)  
Birmingham Workhouse Infirmary.—Assistant Resident Medical Officer. Salary £100 per annum, with apartments, rations, coals gas, laundry, and attendance.  
Bradford Children's Hospital. House Surgeon. Salary £100, with board, residence, and washing.  
Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence. Also Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.  
County Asylum, Lancaster.—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, with apartments, board, washing, and attendance.  
Eastern Counties' Asylum for Idiots, Imbeciles, and the Feeble Minded, Colchester.—Resident Medical Attendant, unmarried. Salary £100 per annum, with furnished apartments, board, and washing.  
East Riding of Yorkshire.—County Medical Officer of Health. Salary at rate of £400 per annum, rising to £500 per annum, with allowances. (See Advt.)  
Great Northern Central Hospital, London.—Vacancies for House Physician. Salary £60 per annum; Junior House Physician, Salary £30. Board, residence and washing provided in each case. Also Junior House Surgeon, Salary £30, with board, residence, and washing; and a non-resident Assistant House Surgeon, with Salary at rate of £30 per annum, and partial board. Full particulars of these vacancies will be found in our advertisement columns.  
Johannesburg.—Medical Officer of Health. Salary £1500 per annum.  
Northampton General Infirmary.—House Physician, unmarried. Salary £100 per annum, with apartments, board, attendance, and washing.  
Salop Infirmary, Shrewsbury.—House Surgeon. Salary £100 per annum, with board, washing, and residence.  
Scarborough, Borough of.—Medical Officer of Health. Salary £325 per annum, rising to £375 per annum.  
Stamford, Rutland, and General Infirmary.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.  
Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary £100, with board, lodging, and washing.  
Township of Manchester Workhouse, Crumppall.—Junior Resident Assistant Medical Officer. Salary £110 per annum, with apartments, fire, light, washing, and attendance.  
University of Glasgow.—Examiner for Degrees in Medicine and Science, with special reference to Physics. Salary £30.  
Victoria Hospital, Folkestone.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

### Births.

GODSON.—On August 9th, at Linden House Cheshire, the wife of John H. Godson, M.R., B.S.Camb., of a daughter.  
GREEN.—On August 17th, at 2, West Hill, Sydenham, the wife of H. Melville Green, M.D., of a daughter.  
HAWKINS.—On August 5th, at London Street, Reading, the wife of Francis Henry Hawkins, M.D.Edin., M.R.C.P.Lond., of a daughter.  
NEWBOLT.—On August 13th, at 42, Catherine Street, Liverpool, the wife of George Palmerston Newbolt, M.B., F.R.C.S., of a son.  
SCOTT.—On August 13th, at Hurstpierpoint, Sussex, the wife of William John Scott, L.R.C.P.I., of a son.  
WAGHORN.—On August 19th, at 8, Glenluce Road, Blackheath, the wife of J. W. Waghorn, L.R.C.P., R.N., of a daughter.

### Marriages.

HATCH—PACKE.—On August 14th, at St. Andrew's Church, Wilmcote, Stratford-on-Avon, Herbert Lincoln Hatch, M.B., of Johannesburg, to Maud Elizabeth, elder daughter of the late Charles Lewis Packe, Esq., of Harefield, Middlesex, and of Mrs. Jucefix, of Wilmcote Vicarage.

### Deaths.

BELL.—On August 16th, at 1A, Cavendish Road, St. John's Wood, London, Alfred James Bell, M.R.C.S.Eng., L.R.C.P., aged 55.  
BOULTER.—On August 7th, at Farquhar Road, Upper Norwood, Samuel John Boulter, M.R.C.S., L.S.A., aged 83 years.  
BROWN.—On August 16th, at Clarence Road, Southsea, Fleet-Surgeon William Brown, R.N., age 155.  
FRANCIS.—On August 10th, at Spencer Park, in his 81st year, Charles Richard Francis, M.B.Lond.  
SWETE.—On August 9th, at Castle Hill, Fishguard, Pembrokeshire, Horace Lawton Swete, L.R.C.P.Lond., J.P., eldest surviving son of Horace Swete, M.D., of Weston-super-Mare and Dunmarklyn, co. Cork.

## Original Communications.

### SOME OBSERVATIONS ON THE ÆTIOLOGY AND PROPHYLAXIS OF ENTERIC FEVER IN SOUTH AFRICA,

MORE ESPECIALLY THE COLONIES OF  
NATAL AND THE TRANSVAAL.

By E. BLAKE-KNOX, B.A., M.D., B.Ch., B.A.O.  
(Univ. Dubl.), L.M.,

Formerly Asst. to Lecturer in Pathology and Bacteriology, Trinity  
College, Dublin; Lieutenant, Royal Army Medical Corps.

Of the prevailing diseases met with during my recent tour of active service in South Africa, by far the most prominent in its severity and medical importance has been typhoid or enteric fever. Statements as regards the ætiology of this fever and its prevalence in respect to South Africa, more especially the colonies of Natal and the Transvaal before the commencement of hostilities which I have had access to, do not in all cases hold true when contrasted with the conditions under which these countries have been placed while in a state of war.

Before the war enteric was said to be very prevalent, especially in the high lands. It was epidemic during the Zulu war, at Utrecht, and after the last Boer war at Newcastle, Pietermaritzburg, and Ladysmith, while garrison stations have always suffered year after year. February, March, and April are said to be the months of greatest prevalence; those of November, December, and January ranking next. The civil populations and natives were said to suffer severely, so that towns and kraals were to be regarded as suspicious foci.

During this war, previous to embarkation, each officer of the Royal Army Medical Corps was furnished with a memorandum prepared with elaborate trouble by the Medical Department of the War Office, and having reference to the probable diseases to be met with in South Africa, and suggestions as to the prophylactic and other measures most suitable to be observed. In this memorandum it was pointed out that the streams and rivers were constantly polluted by adjoining habitations and also by the carcasses of dead animals, and that an equally potent cause was the neglect of conservancy arrangements and the constant pollution of soil that is taking place. One of the chief sources of infection in camping grounds being the urine of people who are suffering from, or who have suffered from, enteric fever. It was laid down that the best prophylactic measures for medical officers to follow was to see that in all camps, especially standing camps, an intelligent and daily use of disinfectants be followed, that sanitary supervision of the strictest possible nature should be adopted on the following lines. That in addition to the usual precautions required in connection with water supplies, such as boiling and filtration, the daily use of disinfectants in all latrines, urine tubs, soakage pits, &c.,

becomes essential. For this purpose quicklime was recommended as the best material to be used. It was to be added in the form of freshly prepared milk of lime (one part hydrate of lime to eight parts of water), the quantity to be added to urine tubs, soakage pits, latrines, &c., should be, roughly, in the proportion of one part milk of lime to twenty parts of the contents of buckets, receptacles, pits, &c.

The milk of lime was to be sprinkled freely on the surface of the soil in the neighbourhood of latrines, and wherever surface pollution was likely to take place. Another important point was the protection of food from the contamination of flies or faecal dust. Kitchen refuse was never to be allowed to accumulate, but was to be immediately burnt, and wherever flies appeared to congregate it was to be taken as an indication that refuse or other organic matter was present, and that steps were to be taken to use strong disinfectants to destroy if possible the flies breeding there.

Many other valuable suggestions, which time and space will not allow me to enumerate, were laid down in this memorandum, so that in this particular campaign it was endeavoured to move a step in advance of previous campaigns in the methods of obtaining, above all things, a pure water supply for the troops; the second precaution advised by the Medical Department to the War Office was the provision of a filter suitable for troops on the move. Many of the so-called sterilising filters used in previous campaigns have been next to useless; they get out of order, the candles break, they get coated with mud, they are heavy and difficult to carry about, and generally, as experience has shown (for example, in the Ashantee campaign), they were left at the base as useless. The Medical Department, on careful consideration, recommended the adoption of the Berkfield filter. This filter was tried for the first time at the Salisbury Plain manoeuvres of 1899, and though open to some objections for field service was by far the best filter in the market. This Berkfield filter was designed to filter thirty-four pints in ten minutes, and was sufficiently light to carry with troops. One was to be supplied to every unit of 100 men, and was supposed to be able to be brought into operation whenever a pool or any water which might be a source of water supply during the march was found. It was supposed to filter water at a sufficiently rapid rate to give each man of a unit of 100 men a fair quantity of drinking water within thirty minutes or hour of the halt.

But having the defects common to sterilising filters for troops on the march, it cannot be worked perpetually, the candle gets clogged, and the more clogged it gets the more difficult it is to work, and it was to rest with the men themselves to organise a method of passing this filter from man to man and keeping it cleaned.

The third prophylactic measure I will mention advised by the Medical Department, which, although as yet in its infancy, was that of vaccination of the troops by an anti-typhoid vaccine prepared in the laboratory of Professor Wright at the Army Medical School at Netley.

The principles upon which this anti-typhoid inoculation is based by him are as follows:—First, laboratory experiments have clearly proved that animals inoculated with dead cultures of typhoid bacilli have a greater

power of resisting infection from living typhoid bacilli than animals not inoculated. It may be inferred that this rule will hold good with man from the fact that the anti-typhoid inoculations induce in man precisely the same blood changes which they induce in animals. Secondly, the blood changes which occur in man by anti-typhoid inoculation are precisely the same as occur in him by an actual attack of typhoid fever. The importance of this last fact becomes apparent when it is considered that the insusceptibility against further attack, which supervenes upon an actual attack of typhoid fever, is almost certainly dependent upon the occurrence of the particular blood changes which are here in question. While at Netley I had the opportunity of seeing the preparation of this serum and personal demonstrations on the means of inoculation.

The vaccines are prepared from sterilised typhoid cultures grown either on agar-agar or nutrient broths of various compositions, the strength of each vaccine is ascertained in the laboratory by inoculation on animals, and a small quantity of antiseptic is added to it to provide against all possibility of contamination. It is then put up for use in either sealed glass capsules for one or two vaccinations, or in glass bottles covered with paraffined indiarubber caps, containing enough serum for occasions when a number of inoculations are to be made at once. The vaccine is sterilised in these bottles before it is sent out. Vaccinations against enteric not being compulsory in the Army, it was suggested to the various medical officers to call for volunteers among the officers and men of the units going out to the war; some were inoculated before going out, others on board the transports, and some in South Africa. Lectures were given in which the medical officers explained in as concise and familiar terms as possible the objects and expectations of inoculation. A call was then made for volunteers, their names taken, and inoculation made in batches, a careful record was entered of each man with his age, number, and name of his regiment. While on passage out in H.M.T. *Divaara* I made a number of inoculations chiefly among the officers and men of the Royal Lancaster regiment and 11th Brigade Bearer Company in conjunction with Captain Tyache, R.A.M.C., following the usual methods as laid down by Professor Wright. The men were taken in batches of five, the flank of each being the site chosen for injection, on account of the looseness of the subcutaneous tissue here, and also from the fact that owing to a certain amount of pain and effusion which follows inoculation, it is always better to choose a site which lies on a more or less protected part from friction or joint movement. The skin having been first made surgically clean, the serum was injected from a hypodermic syringe which had been sterilised in oil at a temperature of 140° C.-160° C.

A thick fold of skin is then pinched up between the finger and thumb, and the needle passed down well into the subcutaneous tissues in the centre of this fold, after the necessary amount has been injected the needle being gently withdrawn, the track left by the needle in the skin should be gently squeezed from without inwards. This last proceeding I think most important, as from the fact of the needle being a large one I have several times noticed a reflux of the serum down the track of the needle, either at its withdrawal or even some time after. Such a reflux as this occurring might easily be overlooked and the case registered as inoculated, and such a subject contracting enteric fever some time in the future and perhaps dying would bias the opinion of some people as regards the advantages of inoculation.

The clinical signs and symptoms which result from anti-typhoid vaccination are subject to considerable individual variations, and can be divided into constitutional and local. Of the former, most cases manifest some degree of malaise, and some even faintness or vomiting; some few show definite rigor. This symptom generally comes on from four to six hours after inoculation. Temperature is seldom below 101° F., and may rise to 103° F., but generally subsides within twenty-four hours. The local symptoms are much the same in

all cases—local effusions at the site of inoculation, heat, redness, swelling, pain—but all pass away within forty-eight hours. Most of my cases I did at 10 in the morning; all turned up for their mid-day meal, some feeling a little stiff in the side, about 25 per cent. were absent from their evening meal at 6 p.m., and those who were present were decidedly sore and stiff. The absentees, on going to inspect them, were found lying up in their bunks, their chief complaint being that they were too stiff to get up. Of several hundred cases vaccinated in no case did any suffering occur after forty-eight hours from the time of inoculation. Professor Wright has pointed out in his memorandum issued on the subject of vaccination the importance of the considerable additional protection derived from a repetition of the inoculation at a later date not earlier than eight or ten days from the first injection. This I was unable to carry out owing to more men coming forward for inoculation than was expected. Finally I inoculated myself, and though somewhat sick and sore for nearly forty-eight hours, I was able to continue my routine duties and eat my meals.

Having now briefly discussed the main precautions laid down before the war by the Medical Department, I shall endeavour to add my own personal observations on the fruits borne by the same during the campaign. My observations are limited to the period commencing December, 1899, and terminating February, 1901, and the ground covered may be taken as fairly typical, as I have been in all four colonies. I will first deal with the subject of inoculation. That inoculation has been a success I have no doubt, but this will be a subject that will require lengthy statistical reports which cannot be completed until the termination of hostilities, for many of the cases entered in the army returns as enteric, and many other cases entered as other kinds of fever, will have to be looked into, for it must be remembered that many obscure fever cases have been diagnosed as enteric in persons who have been previously inoculated. And it must be kept in view that Widal's reaction, when obtained in a person who has been previously inoculated, does not in any way confirm the diagnosis of typhoid which may have been arrived at by ordinary clinical methods. And much less does it conclusively prove the correctness of such diagnosis. In view of the difficulty which has often arisen in diagnosing enteric in inoculated people, it must be the reduction of actual typhoid mortality that must be taken and not the reduction of the presumed cases of typhoid itself among inoculated persons. With this view I have always made it a point to carefully examine all enteric cases in hospital which had been previously inoculated. From the evidence I have collected I am of opinion that the following results will be found true in the vast majority of such cases:—

First, that inoculated cases as a rule run a mild course, and such complications as high fever, hæmorrhage, and perforation rarely occur, i.e., that there is a very great increase of bactericidal power in properly inoculated men.

Secondly, that severe cases of enteric occurring among inoculated men will always leave a history of no distress at the time of inoculation, pointing to the likelihood of the vaccine not taking. None of the cases I either inoculated myself or saw inoculated have died from enteric to my knowledge, and none of these cases to my knowledge have been inoculated a second time.

Passing from the subject of inoculation to the water question we come to what is really the crux of the whole question of our heavy mortality lists in South Africa. The water available for drinking in that country, south of the Pretoria-Delagoa line, is distinctly bad, having one ever present ingredient, namely, mud. In the Lydenburg district, north of this line, the water we met with was pure and of a crystalline sparklency, and wholesome where not poisoned, as I have found it on several occasions, with the ferro-cyanide of potassium used in the mines. The water, which had to be used by the Natal Field Force in its twelve months' journey, had to be drawn from sources previously occupied and contaminated by the Boers. It had to be drawn either

from small rivers or pens, the latter being marshy pools, and was always of a dirty brown colour. The amount of mud in this water was always enormous, even when the water was drawn from a river the size of the Tugela. Mud never at any time being a favourable adjunct to the food of man, he not being a sutorial animal, and acting as an irritant to the intestinal tract, produces an acute gastro-intestinal inflammation which always results in diarrhoea. An acute gastro-intestinal inflammation produced by muddy water is accompanied by

1. Catarrh of mucous membrane.
2. Congestion of the vessels.
3. Spasmodic contraction of the muscular coats of the gut.
4. Development of gas in the interior from the decomposing matter in the water.

Catarrh of the mucous membrane is very apt to spread to the orifice of the common bile duct, and may cause a catarrhal jaundice; this accounting for the many cases of jaundice which have occurred. Congestion of the vessels, especially those of the rectum, when associated with diarrhoea, tenesmus, and flatus, often tends to hæmorrhage; this is materially assisted by the conditions under which a soldier is placed while on the march; he procrastinates the act of defæcation until the last minute, as at least two belts and other impedimenta have to be taken off, and this, followed by a hurried evacuation, results in a bloody and mucous stool of very much the same appearance as that found in dysentery. Acute gastro-intestinal inflammation easily tends to become chronic; this is especially manifest and aggravated in troops fed on preserved field rations and biscuit. When the chronic stage is reached the condition of affairs is most grave. From faulty digestive power the patient emaciates and becomes much debilitated, and the condition of the mucous membrane of the intestines is such that a most suitable nidus is presented to the germs of enteric or dysentery should they be present in any further water drunk. Should such a patient become infected and should he not report sick, as is often the case, especially during fighting (for during such times "Tommy" won't report sick unless he is really "very sick"), let us see what happens. The patient defæcates in the nearest donga; in a hot climate the stool rapidly dries, and is either blown about by the wind or washed by the first heavy rain into the nearest water supply, ready to infect the next comer who draws water from it. So these diseases spread.

During the dark days of the three months preceding the relief of Ladysmith, the water question added itself to the numerous difficulties that General Buller and the Natal Field Force had to contend with. Until the Tugela was crossed no available water was fit for drinking at either Chieveley or Frere; it had to be brought by train in specially constructed trucks and carried thence in tanks on ox wagons to the troops and dealt out sparingly.

At Spion Kop it was the lack of any kind of water, in combination with the untenable nature of the position, that led to the evacuation of the hill. Even when the Tugela was reached the water of that river was contaminated by corpses and dead animals, and was of a deep brown colour from the amount of mud it contained. Berkfield filters, or, in fact, any artificial filters were soon found to be useless. They became clogged after a few pints had passed through, and could not be used. Fuel was so scanty that it took the troops all their time to find that necessary for cooking purposes. Fires could not always be lighted owing to the close proximity of the enemy, as any smoke rising above a hill crest was sure to draw shell fire. During the fourteen days preceding the battle of Pieter's Hill the entire army were huddled together in a valley through which the Tugela ran. Putrefied corpses of horses, cattle, and men contaminated every donga leading to the river, as well as the river itself. The Boers had also been camping in this ground for the previous three months. Torrents of rain fell daily, washing all kinds of contamination into the river, which at that time was then our only water supply.

The sewerage and offal of fever-stricken Ladysmith and Intombi Hospital passed by means of the Klip River also into the Tugela.

Such a condition of affairs gave the medical officers of the Natal Field under Colonel Sir Thomas Gallwey their utmost to cope with, in addition to their already heavy work attending the wounded. It had to be done, and it was done, and yet no epidemic of enteric of any proportion occurred.

When Ladysmith was relieved on February 28th, 1900, it was found that the garrison of that unfortunate town had suffered severely from the water question, and had it not been for the prompt sanitary action taken by the medical officers at the commencement of the siege a still greater amount of sickness would have occurred. As it was, 1,700 soldiers contracted enteric out of a force of 12,000, and about 1,800 contracted dysentery. The only source of water supply in Ladysmith was the Klip River, the water of which was of pea-soup consistency, due to the suspension of large quantities of red mud. Major Westcott, R.A.M.C., who acted as special sanitary officer during this period, in his report on the analysis of the water available there, reports that the water from the Klip River, though notoriously suspicious in quality, only contained one grain per gallon of chlorine, indicating an almost entire absence of organic matter, thus contrasting very favourably with that from a crystal stream on which he was called to report near the gorge of Ladysmith, which contained fourteen grains per gallon, and that from a well in Intombi Sprint, which contained twelve grains per gallon, both of which, of course, were unfit for drinking purposes. As, however, the small extent of animal contamination was no indication of the absence of the typhoid poison, the water of the Klip river was sterilised before the drinking by filtration through Berkfield filters. The mud was precipitated by alum, as long as it lasted, but on December 18th all the available alum was used, and another plan of clearing the water previous to filtration was adopted, which proved to be a great improvement on the previous process. Five open hog-heads were sunk in the river bed at different levels, with the result that there was a constant supply at all water levels of perfectly clear water; this was pumped by the fire-engine into tanks on the bank of the river, of a total capacity of 5,000 gallons. Two water-carts made constant journeys to the filters, which by working day and night gave a daily supply of 1,500 gallons, which was ample for drinking purposes. Each unit also drew from the tanks one gallon per head of clear water for drinking purposes. In connection with the influence of water supply on the causation of enteric, Major Westcott noted that when the men in Ladysmith were supplied with filtered water there was a distinct drop in the admissions for dysentery, while those for enteric fever continued to increase.

On the arrival of General Buller's army in Ladysmith it was manifestly impossible from a sanitary point of view to quarter his troops in the town, and he broke his force up into brigades and stationed them within a convenient radius; some were placed on the line of the Tugela, others at Sunday River, Smith's crossing, Acton Homes and Elands Laagte. It was to the last-named place the 5th Division, to which I was attached, was posted.

The water at Elands Laagte being anything but good, and the health of the troops not being as satisfactory as might be wished after their exposure and precarious living for the last few months, I was asked by the General commanding the 11th Brigade to undertake special duties with regard to water supplies and general sanitary work in the camp, and to furnish him with a detailed list of suggestions dealing with these matters. After enumerating many of the points I have mentioned in this paper, I suggested the following remedies:—

1. *Diarrhoea*.—That any soldiers suffering from diarrhoea should in every case report sick as early as possible and come up for immediate medical treatment, as such cases, with proper therapeutic and dietetic treatment, are easily cured in the early stages, whereas the difficulty of curative treatment is greatly increased

should the ailment be allowed to go on untreated, even for a few days. The dietetic treatment consisted in substituting a milk, cornflour, and soup diet, instead of the ordinary meat, bread, and vegetable diet in a standing camp.

2. *Water*.—All water supplies to be daily inspected and marked by distinguishing flags. That three separate and distinct water supplies were to be recognised, water for human drinking and food purposes water for animals and water for washing, that sentries were to be posted over each of these to see that no interchange was to take place between the uses each pool was allotted to. That all water used for human drinking purposes was first to be cleared of mud by either precipitation by alum, ten grains to the gallon, or passed through mechanical strainers; for this purpose I advised that clean empty barrels, of which we had sufficient number, be utilised. One barrel to be sawed in half in such a way as to form two tubs, each tub was to have a foot square cut out of the bottom, and the aperture covered by a number of layers of fine linen or khaki, this tub strainer was then to be placed over another complete barrel which received the strained water, and the water finally drawn off by a tap below came out clear. This water was now to be passed through a Berkfield filter through which it now easily ran, and it was finally to be boiled if possible. Cleansing of water carts and the men's water bottles with permanganate of potash at intervals was also recommended.

3. *Disposal of Refuse*.—Strict orders were to be enforced as to men using only the recognised latrines and urine tubs, and the proper disinfection of the same with chloride of lime. All kitchen refuse, including preserved meat tin cans, were to be deposited in pits dug for the purpose, and to be burnt. All animal refuse was to be removed some distance out of camp before 8 a.m. daily, and to be burnt when dry. All dead animals were to be taken some miles out of camp and buried at least under three feet of soil. As number of dry fœtid carcasses of horses lay about the battle-field of Elands Laagte from General White's engagement in the previous year, the most effectual method of destroying them was found to be burning.

4. *Inoculation*.—Recommendation of inoculation to all, especially young soldiers, with anti-typhoid serum, is advisable. Major-General Wynne did all in his power to assist the medical officers in their sanitary duties. He embodied the suggestions I have enumerated in camp orders, and paid daily visits of inspection to the various camps.

On May 12th I was appointed to Lord Dundonald's cavalry brigade, and with this I remained for the following six months. This brigade consisted chiefly of colonial troops; it comprised "A" Battery Royal Horse Artillery, Strathcona's Horse, South African Light Horse, Thornycroft's Mounted Infantry, Bethune's Mounted Infantry, Stewart's Mounted Infantry. As it will be of interest to contrast the health of these irregular cavalry with the infantry I had been the previous six months with, I will first give an outline of the composition of each of these regiments. "A" Battery, R.H.A., consisted of men who had been for some time in India at Umballa. Most of them had had malaria at some time or other. The South African Light Horse, as well as Thornycroft's and Bethune's Mounted Infantry, were all enlisted in South Africa and comprised men of remarkable wiry physique, but of very variable ages. Although a large proportion of them were Africans either by birth or adoption, many of the men came from other colonies. This was particularly marked in the South African Light Horse, a number of whom were Australians. Stewart's Mounted Infantry consisted of mounted troops drawn from a number of our regular infantry regiments. Strathcona's Horse was a regiment of Canadians of particularly good build and physique. They were all big men and drawn from the north-western districts of Canada.

During General Buller's continuous advance through Northern Natal into the Orange River Colony, and finally through the Eastern Transvaal, Lord Dundonald's Brigade acted as the advance guard of the army and did all the scouting. We were

also responsible for the selection of water supply and camps and the sanitary conditions of the same which was necessary for the preservation of the health of the main army when it came up. Colonel W. B. Allin, R.A.M.C., Principal Medical Officer of the Natal Field Force, is to be congratulated on the results of his labours in this direction, for no camp for the main army was selected without his first making a thorough investigation of its water supply and other hygienic surroundings, this added to the amount of attention paid to the food and blankets of the men, although hampering General Buller with additional transport (he carried 1,503 medical diets with the Natal Field Force after the line was left in the great advance north), such things greatly helped in reduction of sickness in the Natal Field Force; the statistics of which will very favourably contrast with any other field force or any other campaign our troops have been in. I was with the cavalry for more than six months, and was agreeably surprised at the very small amount of sickness in Lord Dundonald's Brigade. At the same time it must be remembered that any comparison between cavalry and infantry in a campaign in the matter of health and admissions to hospital is hardly fair. The mounted man naturally does not suffer so much from fatigue and thirst as does the foot soldier, who madly rushes to drink any water, no matter how muddy, he meets with on the march, stirring up the mud and thus still further polluting the water in his endeavours to fill his water-bottle. The hardened infantry reservist bears a favourable comparison with the infantry recruit in this respect on the march. While the former by experience has learned that he can march easier and perspire least if he keeps from water during a march, and whom you may see at a halt cool and refresh himself by merely rinsing his mouth with water, and not swallowing it; whereas the recruit hugs his water bottle as his most cherished possession, he fills it at every puddle he can get to, and empties it with the same avidity as an infant does its feeding bottle. The result of continuous water drinking to the recruit is much discomfort, heavy sweating, and exhaustion, and these are the men who fall out on a march and fill up the ambulance wagons. From what I have seen I would be almost tempted to take the water bottle away from the recruit on foreign service. Another, and perhaps the best, explanation as to why this Colonial Brigade contrasted so favourably with the infantry was that so many of the men in it, being South Africans, had become inured to the climate and muddy water through long residence in the country, or had been used to country life in some of our colonies. Another explanation might be the fact of mounted men constantly moving from one camp to another.

There is little further of interest to relate on the water question until General Buller advanced north of Lydenburg. Here, while acting as advance Sanitary Officer of the Force, I had reason there to condemn certain water supplies in several places, as they had been poisoned by cyanide of potassium. Lord Roberts had previous to this drawn the attention of the medical officers of his force to this possibility occurring in the advance through the enemy's country. But I am not sure if any water was found poisoned on his side. The tests I employed were the ordinary ones, a ferric salt giving a blue precipitate with ferrocyanide of potassium. The precipitate insoluble in dilute hydrochloric acid and decomposed by a solution of caustic soda; cyanide of potassium also renders water alkaline. The large amount of iron naturally existing in the water of the Lydenburg district made the poisoning of running water extremely difficult. In conclusion I would like to remark, notwithstanding the fact that a sanitary officer has been condemned by Lord Wolseley as a useless encumbrance in time of war, I think the campaign in Natal has clearly proved that, with the co-operation of the general staff and the principal medical officer in the first place in selection of camps, feeding, and clothing, and secondly, what is even more important, the co-operation of regimental commanding officers with their regimental medical officers, has proved the value of the present system. This could no doubt be perfected by the

allotment of one or two medical officers to the staff of the principal medical officer of a field force, which officers would be made responsible for daily sanitary inspection of all standing camps, camping grounds and hospitals, and conduct water analysis, report on food and clothing, and do medical and surgical research work. *They could report direct to the Principal Medical Officer on the spot and assist him, not only in sanitary matters, but be available in times of urgency.*

THE THERAPEUTIC AND DIAGNOSTIC VALUE OF TUBERCULIN IN HUMAN TUBERCULOSIS. (a)

By G. A. HERON, M.D., F.R.C.P.,

Physician to the City of London Hospital for Diseases of the Chest.

IN the autumn of 1890 there took place in Berlin one of the most remarkable events that mark epochs in the history of medical science. The announcement of a new method of treating tuberculosis by the man who shared with Lister and Pasteur the honour of having done most for the advancement of scientific medicine and the consequent lessening of human suffering. With much enthusiasm, and with high hopes of its future usefulness, tuberculin was received in the autumn of 1890. Before the end of the following spring the remedy had to a very great extent fallen into disuse, and was damned as loudly as it had ever been welcomed. The outcry against the use of tuberculin—for it was nothing less than this—had for its chief cause the condemnation of its use by another distinguished German, Virchow. The patriarch of present day pathologists said that, in his opinion, the use of tuberculin was fraught with danger to the patient. His reason for making this statement was that he had seen in the bodies of consumptives, who in life had been treated with the old tuberculin, evidence which convinced him that the drug caused destruction of the tissues around tuberculous centres, and so set free the bacillus to do its work upon healthy tissues. Virchow maintained that, had the remedy not been used, the bacillus might have rested, harmless, encapsuled, as we know it often is, by tissues that have undergone an indurative process, and become fibrous. Now this statement of his views by a man so justly famous as Virchow at once attracted attention. There is, I think, no doubt that this expression of opinion greatly tended to deter men from using tuberculin, and to prejudice the medical profession everywhere against its use. And so tuberculin was both made and unmade in Germany!

Of Virchow's objections to the employment of tuberculin I can only say that, in my hospital experience of its action, there has been observed no evidence of resulting spread of disease to seemingly healthy organs, or to neighbouring tissues. The average stay in hospital of the first thirty-five cases treated with old tuberculin by me extended to sixty one days. There was, therefore, sufficient time in which to observe whether or not, in these cases, there was to be obtained clinical evidence in support of Virchow's views. In no case was this evidence found,

and it was often searched for by other physicians besides those officially present in the wards.

It may be worth while to refer in this connection to a case treated by me with the new tuberculin in hospital, and selected for that treatment because the patient was certainly slowly dying of extensive and advanced tuberculosis of both lungs. Dr. Perkins, who is one of the honorary secretaries of this section of the Congress, and was then pathologist to the City of London Hospital, performed the post-mortem examination. He made special search for the presence in the viscera of centres of probable fresh tuberculous infection, but found none. This patient received twenty-six injections of new tuberculin in forty-two days, and the doses ran from  $\frac{1}{100}$  mg. up to 2.5 mg.

Koch had, in the plainest words, and on several occasions, stated that cure of tuberculosis when it affected the lungs could be reasonably looked for, with the help of tuberculin, exclusively in those cases where only a small portion of one lung was infected to a slight extent, and where, of course, there was no evidence of excavation of lung tissue. He also said it would be reasonable to hope for a cure when only a small portion of each lung was diseased, there being no evidence of excavation. Any departure from these types of cases in the direction of increase of the extent of the disease, lessened by so much, in Koch's opinion, the chances of a cure; although even in more advanced cases amelioration of symptoms was, he believed, likely to result from the use of the remedy. Now hospital experience taught me that it is seldom we have there an opportunity of treating these early cases. Therefore it is not common to find in hospital the cases in which cure of the disease can be reasonably expected. So far as my experience of private practice goes, I must say the majority of cases in which I have been asked to advise as to the use of tuberculin have been too far advanced in tuberculosis to permit of high hopes for the best result of the treatment being obtainable. But when in unsuitable cases the use of tuberculin produces no good result, blame should not rest on the remedy.

In my opinion, tuberculin has fallen into discredit: 1. By its frequent use in unsuitable cases. 2. By its administration in too large doses. 3. By neglect of the rule that a dose of it should never be given until the patient's temperature has been normal for the previous twenty-four hours at least. 4. By neglect of the rule that the dose of tuberculin should never be increased, but, on the contrary, should be diminished, when its administration has been followed by a rise of temperature. 5. By the prejudice raised against the remedy, among both doctors and patients, because of the severity of the symptoms which not seldom follow upon its use.

In consequence of a long illness, which, until a fortnight ago, unfitted me for work, I was obliged to relinquish the treatment of the cases I had begun to observe for the purposes of this discussion. Therefore, I am unable to present to you the new work which it was my earnest wish and intention to have submitted to you to-day, and I can deal only with work I have already published. Since the end of 1890, fifty-seven cases have been treated with tuberculin by me at the City of London Hospital for Diseases of the Chest. Fifty-one of these were examples of tuberculosis of the lungs, and six of lupus vulgaris. Of these, five of the lupus cases and twenty-seven of the others were treated with old tuberculin. One case of lupus and twenty-four cases of tuberculosis of the lung were treated with the new tuberculin. At the end of the year 1900 seventeen of the fifty-one cases of lung disease had been lost sight of, practically from the time they left hos-

(a) Abstract of Paper read before the British Congress on Tuberculosis, July, 1901.

pital. Sixteen of the remaining thirty-four were then known to be well, and earning their living. I ask you to bear with me while I touch upon a few of the more important features—as I deem them—of these cases.

Whether consumptives leave a hospital well or ill is a very small matter compared with the answer to the really important question: How many of these people are able to work for their living, and for how long a time did they continue to gain their livelihood? I think the return to useful life of sixteen out of thirty-four cases of tuberculosis of the lungs is not altogether an unsatisfactory result of treatment, and this result was obtained with the help of tuberculin. According to our information at the hospital, ten of these sixteen cases of recovery are known to have remained well and able to work for seven years, three for over three years, and three for nearly two years. Other patients remained able to work for periods varying from a few months to eighteen months, but as they are known to have broken down in health they are not included among these sixteen cases of apparent recovery.

Thirty-two of these fifty-one cases left hospital in 1891. Seven years afterwards—in June, 1898—the information concerning these cases, obtained, for the most part, by the assistant medical staff and nurses of the hospital, was as follows:—Eight of them were dead, ten were well, one relapsed in 1897, having remained well until the autumn of that year, thirteen were lost sight of very soon after they had left hospital.

These patients were all treated by the old tuberculin, and their cases are dealt with in some detail in a paper I contributed to Vol. XIV. of the *Transactions of the Medical Society of London*.

In addition to these thirty-two cases, five cases of lupus vulgaris were then treated by the old tuberculin. These cases all did remarkably well up to a certain point, and then, at longer or at shorter intervals, suffered relapse. In one of the five a relapse did not set in until more than a year after she left hospital, and she would not return for treatment because she said she could not afford to give the time necessary for this purpose.

Some of these cases of lupus vulgaris relapsed while under the influence of tuberculin. It is certain that at this period of the history of tuberculin cases of lupus received unnecessarily high doses of the drug. When relapse took place in, for example, three of these cases, one of them had gained 10 lbs. in weight, and was taking 400 mg. doses of tuberculin; the second was taking 1000 mg. doses, and had gained 10 lbs. in weight; the third had gained 18½ lbs. in weight and was taking doses of 1000 mg. These large doses were given once in a week or a fortnight, and were in these cases not followed by high temperature, nor by other symptoms due to the action of the drug. The patients had been respectively 124, 128, and 135 days in hospital, and had received in that time the first-named 50, and the other two 59 hypodermic injections of old tuberculin. It seems to me difficult to believe that these large doses could have exercised any material influence in the direction of favouring any tendency to relapse. The evils said to result from tuberculin are ascribed to its violent effects upon the tissues, by which, during severe reactions, infection of neighbouring healthy tissue is, according to Virchow's observations, apt to happen. But in these cases there were certainly no reactions when large doses of tuberculin were given, beyond slight redness round the site of the lupoid patches. There were no headaches, no rigors, no high temperatures; and yet, in these circumstances, a relapse did take place, and while the drug was being administered. If the

tubercle bacilli were let loose into the tissues, near the patches of lupus, as a result of severe reactions early in the treatment of these patients, then the drug should, one may reasonably urge, have had ample opportunity to exercise a beneficial influence, owing to the administration of the very large doses, which were not followed by reactions worth noticing. Certainly, in all but one of my lupus cases, tuberculin seemed, after a certain time, to lose its power for good. I confess I have never been able to understand why, in cases which had improved so much, certainly because of treatment by tuberculin, relapse should have occurred while the treatment was in full use.

Since March, 1897, I have used only the new tuberculin. During that year ten cases were so treated in hospital. Two of these cases died. One of them was the man whose case I have already spoken of as having been selected because he was certainly dying. The other eight cases of this year were made up of seven examples of tuberculosis of the lung, and one of lupus vulgaris. They all did very well, and, without exception, left hospital, urging as their sole reason for leaving their fitness for work and their wish to resume work. In December, 1900, three years after treatment, the following was the result of the use of tuberculin in these ten cases:—Two were dead, both of them recognised as being hopeless cases from the first; three were well and supporting themselves by their work; three were lost sight of; one remained well until lately, and returned to hospital a few weeks because of a recurrence of disease.

In 1899, ten patients, five men and five women, were treated in the wards with the new tuberculin. Of these five women two are known to be still in good health. One of the two is a domestic servant, the other is a shorthand writer and typist. Two other women are reported to have broken down in health. The fifth has not been heard of since she left the hospital.

Of the men, one continued well for more than a year after treatment, but appears to have recently had a relapse. He worked as a hawker, and so supported himself. Another seems now to be as well as he was when he left the hospital, and is said to be able to work. The third died November 16th, 1900; the cause of death was not stated to us, but he was carried from his work, and two months afterwards died in his bed. Probably he died from a relapse. The fourth was reported to be very ill a year ago. The fifth is working as a photographer's assistant, but he says he had spitting of blood two months ago.

In Krause's record of his six years' experience of Koch's method of treatment of tuberculosis, he states that of twenty-seven of these cases twelve are well, thirteen improved in health, one *in statu quo*, one is worse. It is, of course, not possible on an occasion like this to go into details at any length; but some authors have more or less emphatically dissented from the outcry raised against the use of tuberculin, e.g., Hansen, of Bergen, Osler, Gatsch, McCall Anderson, Petruschky, Spengler, and others. Those of us who have dissociated ourselves from the outcry against tuberculin, have all expressed the view that in cases of tuberculosis, which fall within the limitation laid down in 1890 by Koch, great benefit to the patient is sure to follow upon a proper use of tuberculin, and very often there is complete disappearance of all symptoms of activity of the disease.

Responsible opinion is unanimous in its recognition of the worse than uselessness of any attempt to treat with tuberculin tuberculosis that is complicated with other inflammation. These mixed in-

fections, as they are called, were not recognised in 1890, and it is only within the last few years that their great importance as complications of tuberculosis, whether of the lungs, of the skin, or of any other tissue, has been clearly apprehended.

Is there good ground for the belief that tuberculin, when properly used, is dangerous in any degree to the patient? From my own experience—and I am responsible for over 2,000 injections of it—I am strongly of the opinion that it is, at least, as safe for the patient as is any other very potent drug.

What, then, is the diagnostic value of tuberculin? That it produces its characteristic reaction wherever tuberculosis is present, there can be no doubt. That it rarely fails to react where there is tuberculosis is so true, that cases in which failure is recorded may safely be neglected. In my own experience of this use of it I have never seen any evil consequences follow its administration. It produces no evil effects in such cases as disease of the larynx, nor in kidney disease with albuminuria and glandular tube-casts, nor in disease of the bladder, nor, so far as I know, in any condition of disease, whether tuberculous or not. As an illustration of the practical usefulness of tuberculin as a test in cases always difficult and often impossible of diagnosis by ordinary methods, I would refer to the excellent work done in this direction by Dr. Eric France, of the London County Asylum, Claybury. His object was to ascertain, with certainty, who among the insane inmates of the asylum had tuberculosis. For this purpose he tested fifty-five of his patients with tuberculin. Characteristic reactions occurred in forty-five of these cases. Thirty-four of them eventually died, and twenty-nine of these thirty-four were submitted to post-mortem examination, with the result that, as Dr. France says, "Active tubercle was found in every case." Ten of the fifty-five patients did not react. Five of those died, and post-mortem, says Dr. France, "No trace of tubercle found in any; five still alive and healthy." Here is his expression of opinion on this matter in his own words: "I injected seventy-five cases with tuberculin, and, personally, I am satisfied, not only with the accuracy of its diagnostic power, but also with its entire harmlessness, both in the tuberculous and in the non-tuberculous."

We know that the best, I had almost said the only, chance of cure of the consumptive is to treat him in the earliest days of his illness. It is a fact, that by no other means can we so early diagnose tuberculosis in men as we can by the help of tuberculin. It is also a fact, that we can do this with safety to the patient. Had tuberculin served no other good purpose than this, it would have deserved our best attention, our high appreciation. I am sure the day is not distant when the discovery of tuberculin will be ranked among the most valued of the many gifts mankind already owes to Robert Koch.

## ALCOHOL AND TUBERCULOSIS.

By JOHN C. THOROWGOOD, M.D.,  
F.R.C.P.Lond.,

Consulting Physician to the City of London Hospital for Diseases of the Chest, Victoria Park, &c.

HAVING read the article by Dr. Kelynaek on the above-named subject, in your issue of August 7th, I should like to make a few remarks on the same.

Speaking from experience at the City of London Hospital for Diseases of the Chest, and elsewhere, my conviction is that the moderate use of alcohol in some form or other is helpful in most cases of chronic pulmonary tuberculosis. I have observed excellent effects in checking diarrhoea to follow on the steady use of a rather rough claret as drink with meat food.

If the food be of a milky or farinaceous character

then brandy or whisky may answer better. As a rule, however, I try and avoid spirit drinking, as when once started the patient is very apt to exceed his proper allowance.

Thus I have known a man who was told to take rum and milk every morning go on increasing his dose of rum till he told me he took half a tumblerful of rum filled up with milk as his regular breakfast. Under this regimen his liver attained a prodigious size and the progress of his disease was much hastened. I only saw him once, but soon learned he had died.

The doctor, when allowing spirits, must fix the patient down to a certain daily allowance with a very strong hand.

When there is hæmoptysis all forms of alcohol should be decidedly withheld.

A good single stout of the Romford Brewery I have found a safe and acceptable drink with many patients. This stout is not heady, is really digestible and nutritious, and does not, like ale, cause cough.

Alcohol appears to conduce to the development of fibroid phthisis, and so may bring about the arrest of the disease in its more serious form. I gather that this was the belief of the late Sir Andrew Clark, for I remember the case of a young chemist whom Sir Andrew was kind enough to see with me, and who was seriously ill with pulmonary tuberculosis.

The case was most unpromising, and the only suggestion made to me was to allow plenty of alcohol in his diet in the somewhat forlorn hope that this might cause the disease to take on the fibroid form, and so life would be prolonged.

Gouty people, whose nutrient tendencies are rather to fibroid change of tissue, seem to me very rarely to suffer from tuberculosis.

In one very well marked case of a man who was rapidly going in the lungs, a sea voyage and most generous living quite arrested the mischief, while true gout took its place, the patient becoming robust and plethoric.

Any one who wishes to get the results of some valuable experience on the effect of alcohol in tuberculosis will do well to peruse the remarks of Dr. Thomas Harris, of Manchester, as they are recorded at page 95 of Dr. Ransome's work on the "Treatment of Phthisis."

The subject is one on which one might enlarge, but I mean this paper to be short and practical. Theoretical objections to alcohol as checking oxidation and so forth I do not consider. I dare say chemists and physiologists could make out serious theoretical objections to the use of tea and coffee, and, used in excess, we know both these beverages may do much harm to stomach and nervous system.

## TONSILLOTOMY RASH. (a)

By WYATT WINGRAVE, M.D.Lond.,  
Physician and Pathologist, Central London Throat and Ear Hospital.

THE occurrence of a skin eruption following operations, often referred to as "surgical rash," is familiar to all of us, but its association with the removal of tonsils and adenoids is perhaps not so widely recognised that a few notes may be of interest.

Recent experience of several instances prompted a reference to my hospital and private records which has revealed thirty-four cases in the course of seven years. Although relatively to the large number of operations this is but a small percentage, I feel from

(a) Paper read at the Twenty-third Annual Congress of the American Laryngological Association, held at New Haven, Conn., 1901.

recent experience that they represent but a portion only of those actually occurring, and that a thorough and systematic inquiry would afford evidence of greater prevalence.

It is the custom at our hospital for all patients who are operated on in the extern department to attend, after a week's interval, for examination; and in several instances the parent has reported that the child was kept at home because it had a rash which was thought to be "something catching." Subsequent investigation, however, in most cases proved its innocence of specificity. In other cases the rash was still visible on the patient and unattended by constitutional symptoms.

Of the thirty-four cases, three which were in-patients proved to be scarlet fever, while one developed diphtheria. The remainder were simple non-specific cases.

*Character of Rash.*—The eruption generally appears on the second or third day, either papular, roseolar, or erythematous in type. It most frequently attacks neck, chest, and abdomen, sometimes extending to face and extremities. The earliest appearance noted is on the day following operation; the latest one is on the sixth day. Its duration is generally two or three days, but may extend to five days. After reaching its maximum intensity, it rapidly disappears without desquamation, but is sometimes associated with intense itching.

It may occur at any age—the youngest was four-months and the oldest twenty-three years.

With regard to sex, excluding the specific cases, twenty were females and ten were males.

As a rule there is but slight constitutional disturbance and the child does not appear to be any the worse. In those cases which I was able personally to investigate the temperature was increased  $1^{\circ}$  to  $2^{\circ}$  F.

Although the incidence of so innocent a complication in our most common operation may not be unfamiliar to many of us, I am not aware of any published references having been made to the subject. It is, however a matter of some importance, since foreknowledge will help our diagnosis and prevent any undue precipitancy in forming the graver estimate of its nature.

The occurrence of scarlet fever in three cases and diphtheria in one has, however, an important practical bearing inasmuch as the removal of actively inflamed tonsils is advocated by many surgeons. (a)

There are distinct advantages in this practice, since the prominence of an inflamed tonsil affords facilities to the guillotine, which disappears on subsidence of the inflammation, and there do not appear to be any serious disadvantages. In the absence of any anæsthetic the operation may certainly be more painful, but it most effectually relieves the temporary angina and the removal is thorough. It may happen that tonsillotomy may be undertaken in the early stage of recognised or unrecognised scarlet fever, diphtheria, or other specific fever, and it is maintained by many eminent specialists that not only is no additional risk involved, but that it is an expedient course to take. (b) This may be so if the tonsils alone are removed, but one may reasonably doubt the expediency when a large crop of adenoids requires removal in addition, since the formation of so extensive a denuded surface is not unattended with risk.

The incidence of a rash upon any solution in continuity of tissue, operative or accidental, is well known and has been well discussed, but there are a few points associated with this particular operation which may throw some light upon its pathology.

Examination of the blood during the week following the operation has, with few exceptions, afforded me evidence of an increase in number of the mononuclear white corpuscles. This leucocytosis, which rarely lasts beyond the tenth day, may be more than coincidental, yet it is hardly surprising after so great a disturbance of lymphoid structures. The removal of tonsils and adenoids affords a very large area for absorption of toxic matter.

The rash may also be interpreted as one of drug intolerance, since most of the cases were taking the usual mixture of sodium salicylate and potassium bromide.

Whatever its pathology may be, the knowledge that a rash not infrequently follows tonsillotomy, and that it is not necessarily specific, may be reassuring to practitioners experiencing the phenomenon for the first time.

Since this note was presented eight further cases have been observed and are included in the numbers here given.

## MULTIPLE PAPILLOMATA OF LARYNX. (a)

By N. C. HARING, M.B. Lond., &c.,

Senior Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

*Description.*—The growth occurs in pinkish masses, sessile or shortly pedunculated, affecting the anterior portions of the larynx by preference, but in many cases arising from the whole surface. Most serious are the cases where there is much subglottic growth.

*Incidence.*—It forms a large percentage of the growths of the larynx in children up to the age of puberty, but is not common in adults. As pertains in all laryngeal growths the male is more liable than the female.

*Pathology.*—Microscopically the growth is seen to consist of proliferated epithelium with but little fibrous structure, and may closely simulate epithelioma. There is no infiltration of the contiguous parts. The distinction from a malignant growth, which is difficult in a p. m. specimen, may be almost impossible clinically, as one has to demonstrate that the epithelial cells do not extend below the border line between the laryngeal epithelium and connected tissue.

*Ætiology.*—There is usually no history of antecedent chronic laryngeal disease, nor of any family predisposition. It may appear congenitally. There is strong reason to believe that this growth is analogous to warts on the skin, and especially so in its doubtful relations with epithelioma.

*Symptoms.*—The ordinary ones of laryngeal growth, unless pieces of the growth are expelled during cough, the diagnosis can only be made by obtaining a view. In children where ordinary laryngoscopy may be difficult or impossible, I have found the direct view into the larynx, by means of Korstein's or Escat's tongue depressor, with or without an anæsthetic, almost invaluable.

In children there is little fear of malignancy, but in adults it is necessary to note carefully that there is no fixation of any part of the larynx before the possibility of malignancy can be dismissed.

*Treatment.*—Recurrence is almost certain unless the removal is complete. This endolaryngeal treatment is rarely successful.

Brushing the growth over with phenol sulphocarinic acid, which renders the growth friable, is a useful adjunct to endolaryngeal manipulation.

(a) Abstract of Paper read at the Annual Meeting of the British Medical Association, Section of Laryngology, Cheltenham, August, 1901.

ANALYSIS OF CASES.

Age when first seen	Female, H. W. 46	Male, T. Mc. 11	Male, T. M. (Tom). 9	Male, L. B. (Levi). 4	Male, R. N. (Robert). 3	Female, E. M. (Elsie). 2
Duration of symptoms ... ..	Cough; hoarseness about 6 months.	Hoarseness about 2 years; cough.	Hoarseness about 8 months.	Always hoarse; much worse last few months.	Dyspnoea from birth; hoarse a few months.	Hoarse from birth.
Examination ... ..	Ordinary laryngoscopy; spasm easily set up.	Ordinary laryngoscopy, easy.	Ordinary laryngoscopy.	Direct view; ordinary laryngoscopy impossible.	Ordinary laryngoscopy; severe spasm.	Direct view; ordinary laryngoscopy very diff cult.
Treatment, &c. ... ..	Repeated endolaryngeal. Phenol-sulpho ricinate of no use. Pneumonia probably set up by portion of growth inspired into a bronchus.	Endolaryngeal treatment caused proliferation of growth. Phenol-sulpho ricinate no use. Tracheotomy to relieve dyspnoea; 3 months later thyrotomy, which had to be repeated with complete removal of growth; curette; chromic acid.	Endolaryngeal caused irritation. Phenol-sulpho ricinate no use. Tracheotomy; thyrotomy; scissors; curette; chromic acid.	Tracheotomy after 3 months; thyrotomy scissors; curette; chromic acid.	At present under treatment; phenol-sulpho ricinate; and endolaryngeal.	
Result ... ..	Death from sudden laryngeal spasm.	No recurrence 2 years; good voice; can sing with harsh voice.	No recurrence 5 years; fairly good voice.	No recurrence 14 months; voice strong but rough.	Death from laryngeal spasm 2 days before the day fixed for operation.	

Tracheotomy is often necessary to relieve the dyspnoea, and in some cases is sufficient to cause spontaneous evolution of the growth. For radical treatment I have found thyrotomy most satisfactory. In order to preserve the voice it is imperative to divide the thyroid cartilage in the middle line and to avoid cutting the vocal cords. Spraying with extract of suprarenal capsule much reduces the hæmorrhage. The growth is best removed with curved scissors, the places of origin freely curetted and cauterised by the application of solid chromic acid fused on a probe. Absolute thoroughness of removal is necessary, or recurrence is certain.

France.

PARIS, August 25th, 1901.

THE FRENCH CONGRESS ON GYNÆCOLOGY.

THE French National Periodical Congress of Gynæcology, Obstetrics, and Pædiatrics will assemble for its third meeting at Nantes on September 28-30, under the general presidency of Dr. Sevestre, of Paris, who will also preside over the Section of Pædiatrics. Dr. Segond, of Paris, will be President of the Section of Gynæcology, and Professor Queirel, of Marseilles, of that of Obstetrics. The questions to be considered in the Section of Gynæcology are: (1) Congenital ante flexion of the uterus as a cause of sterility, and its treatment; (2) causes favouring ectopic gestation; (3) dystocia due to fibroids. In the Section of Obstetrics the programme is: (1) Rupture of the uterus; (2) inversion of the uterus; (3) the fate of prematurely born children; (4) the uncontrollable vomiting of pregnancy; (5) radiographic measurement of the pelvis. In the Section of Pædiatrics the following questions will be discussed: (1) Arthritism in children; (2) meningitic manifestations in the course of digestive infections in childhood; (3) intermittent albuminuria in the child; (4) the defence of childhood (pueri-culture, suckling weaning); (5) conservative methods in the treatment of local tuberculosis; (6) scoliosis, its treatment by kinesitherapy (movement cure).

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 24th, 1901.

SPECIAL INSTRUCTION IN BALNEOLOGY.

FOR the benefit and further instruction of physicians a new departure in the teaching of physical therapeutics has been taken in Baden-Baden. The Grand Ducal Government has arranged a ten days' course of lectures and practical demonstrations—at the nominal fee of ten shillings, to defray casual expenses—in the magnificently arranged bathing establishments of that town.

Professor Erb and Professor Rosenbusch, of Heidelberg, will hold introductory lectures, the former on "The Balneological, Physical, and Dietetical Treatment of Nervous Diseases," the latter on "Mineral Springs from a Geological Point of View." Further lectures and practical demonstrations will be held by Dr. Frey (Baden-Baden), "Hydrotherapeutics, their Method and Practical Use"; Dr. Gilbert (Baden-Baden), "Dietetical Treatment and Dietetics in Balneo-therapy"; Dr. Neumann (Baden-Baden), "Hygiene in Bathing Places";

Dr. Obkircher (Baden-Baden), (1) "The Mineral Springs, their Use and Indications, including the New Methods of Inhalation," (2) "Massage, Mechano-therapeutics"; Dr. Boessler (Baden-Baden), "The Chemical Aspect of Mineral Springs, with special reference to Mineral Products, and to the Medical Explanation of the Analysis of Mineral Waters."

The courses will commence on October 14th, and those wishing to take part should send in their names to Dr. Gilbert, Baden-Baden, on or before October 1st.

The *Archiv. f. Gyn.*, H. 102, has an article on

#### PUERPERAL NEURITIS

by Dr. Mattiesen, Leipsic. This disease, according to Möbino, is a paralysis in the region of the median or ulnar nerve, coming on after a normal childbed, in which both sensation and motor power are affected, and especially in the hand most used. The affection commences in childbed sometimes earlier, sometimes later, and after a varying period, always ends in recovery. The lower extremities also may be affected, but to a lesser degree. According to later observation, however, this form of paralysis does not exclusively adhere to this type. Paralysis affecting the larynx and pharynx, the optic nerve, paralysis of the facial and sciatica have also been described.

The aetiology is not known, and treatment in consequence is quite empirical. Prophylaxis also can scarcely be considered, as the gravidity itself is supposed to be the cause. The maintenance of the renal function is considered to be one without influence. Alcohol is to be avoided. The usual anti-neuralgics and anti-rheumatics are useful, and also antipyrine, given, not by the mouth, but subcutaneously. Sodium salicylate acts favourably in the febrile stages, and also on the subjective symptoms. Aspirin may be given to relieve pain. The diaphoresis caused by the salicyl preparation certainly has a beneficial effect in assisting to eliminate the toxin.

The *Munch. Med. Woch.* has an article by Prof. Kehn, Halberstadt, on

#### THE MORTALITY OF OPERATIONS FOR GALL-STONES.

According to the writer the mortality is small so long as the pathological changes are not too extensive and not too far advanced, but it is larger when the affection is complicated by carcinoma or purulent cholangitis. So long as the calculi are limited to the gall-bladder and cystic duct the mortality will not be much above 2 or 3 per cent. If the stones are still in the choledochus the mortality will be higher (4 or 5 per cent.), but so long as there is no diffuse purulent disease operation need not be considered dangerous. The prognosis is, however, just the opposite when the infection reaches high into the bile passages, and when carcinoma is a complication. Simultaneous operation on the stomach and intestines raise the mortality to a possible 20 per cent. if malignant disease is present. If the pancreas is diseased the mortality will depend on the possibility of curing it. The mortality after gall-stone operation will not be further reduced until the cases are brought to the surgeon earlier, and the frequent temporary improvements brought about by treatment in Carlsbad and Neuenahn are a bar to this, as hopes are thereby raised and operative treatment deferred. The experienced operator has a great advantage over the best physician, as the latter rarely has the opportunity for visual and manual instruc-

tion afforded by operation or autopsy. Internal treatment has been but little advanced by advances in knowledge. Now, as before, operations are nearly always performed too late. In the cases seen by the writer the indications for operation have nearly always been empyæma, inflammatory hydrops, frequently recurring colic, chronic closure of the choledochus, adhesive processes, with ectasia of the stomach and pylorus, &c. With these conditions the pathological changes in the bile passages will have been advanced. In the case of malignant complication, also, the opportunity for sufficiently early operation will only be exceptionally afforded to the surgeon, and in a certain proportion of cases neither the physician nor the surgeon will be able to do anything.

The *Klin. Therap. Woch.* has an article on

#### THE MEDICAL TREATMENT OF PERITYPHLITIS,

by Professor Bourget. The professor is opposed to the idea that the onset of perityphlitis is always sudden. On the contrary it may be taken for granted that all affected by the disease have suffered from affections of the bowels and stomach, and that these affections have almost always begun in the stomach, passed on to the bowels, and that the symptoms have lasted months, and even years, before the cæcum or appendix has shown signs of disease. But it sometimes happens that a slight chill to the feet during difficult digestion will set up pain symptoms. The prophylactic treatment of the disease comes, therefore, to the front, and here the first attention must be paid to the diet and avoidance of constipation. The "candidate" for perityphlitis should have a mixed diet, in which flesh meat plays but a small part, whilst vegetables, cooked fruits, and farinaceous foods should form the chief. The fear that fruit seeds would get into the appendix is a groundless one, for the woody seed has a favourable influence on the mucous surface of the intestine, as mucine is formed which facilitates the onward movement of the intestinal contents. The hyperacidity of the stomach must be corrected. This may be done by giving milk gruel or an alkali at the acme of gastric digestion. During intestinal digestion the lower extremities must be kept warm, either by movement or by suitable clothing. The bowels should be opened every day. Saline laxatives are useful - a dessert-spoonful of Carlsbad salts in the morning in warm water. It is better, however, to give a large allowance of cooked fruit with breakfast, and if this is not sufficient one or two castor oil capsules after it. Intestinal irrigation is also useful. Very cold drinks must be avoided even at meals. The author also recommends gymnastic exercises, particularly an auto-massage, consisting in flexing the thigh upon the abdomen when lying on the back, the hands being locked below the knee. This movement should be practiced four times a day, ten to twenty movements each time. On actual onset of symptoms the author advises a treatment based on disinfection of the stomach and duodenum, and washing out of the large intestine. When an attack comes on the patient is put on a liquid diet; 15 to 20 grm. of castor oil are given daily with 1 gr. of salacetyl. If gastric symptoms predominate the stomach is washed out with a 1 per cent. solution of sod. bicarb. When the large intestine is washed out it must be done carefully and so as to avoid pain. Ichthyol is always

used for this in a solution of 4 per thousand. He also uses olive oil containing 1 per cent. menthol thymol in methyl salicylate. After the first two washings the whole fluid is removed; after the third part may be retained. The washings are repeated night and morning. Poultices are applied over the right iliac fossa, and if the swelling is hard and resistant five or six leeches. After the second or third day saline laxatives take the place of the castor oil: sod. bicarb., sod. phosph. anhyd., sod. sulph. anhyd., ana five grms., aq. destill. 1000 grms.; 150 grms. to be given each day in three or four portions.

### THE EFFECT ABROAD OF PROF. KOCH'S LONDON ORATION ON TUBERCULOSIS.

[LETTER FROM J. E. WOLFE, M.D., F.R.C.S.ED., LATE OF GLASGOW.]

WE are here in vacation, nearly all the professors are out of town; some of them will return by the end of this month and others at the beginning of October to resume their clinics. Meantime, the lectures are delivered by their assistants to many English and American students who are working in the various special subjects—eye, ear, throat, skin—in the bacteriological and Pasteur institutes. Some of these assistants are model teachers, who use their large clinical material to the best advantage. These are generally considered as the dog-days in Vienna, but the weather has been pleasant—the thermometer has not risen above 70° to 80° F. in the shade, and the heat is tempered by refreshing showers, making it pleasant for work and outdoor exercise.

Professional opinion here, with regard to Koch's oration at the London Tuberculosis Congress, is partly unfavourable and partly sympathetic. His position is not considered enviable. About twenty years ago he prematurely announced a cure for phthisis by his tuberculin, which Virchow unmercifully proved to aggravate the disease by breaking up local tubercles and disseminating them over the whole system. Veterinary surgeons, nevertheless, have adopted tuberculin as a means of diagnosis in cattle: first, in dairy cows when ailing, or in suspects only, but they have gradually extended the sphere of their operations to the whole bovine race, whether ailing or not. These practices have been carried on without Koch's authority or sanction. Now, after the lapse of so many years, the master pronounces the performances as a flat mistake. This pronouncement has caused great disappointment, especially among his veterinary disciples, and the Professor runs fresh danger, like Actæon, of being torn by his own dogs. In the opinion of some, Koch ought to have first broached the subject at local societies before bringing it up in that great assembly—it was too great a shock to his followers. But he had no alternative; the practices founded upon his teaching have assumed such colossal dimensions, the great interests of mankind are so much involved that he was bound to give his new views the most impressive form. I was thinking of poor Macbeth's moral philosophy:

“— that we but teach

Bloody instructions, which, being taught, return  
To plague the inventor.”

The excitement caused by Koch's oration has served the cause of truth by inducing the German Government to appoint a Commission to examine the whole tuberculosis question, Virchow being one of the commissioners. In his address to the Clinical Society of Berlin Virchow says:—“At that Commission I shall endeavour to establish the difference between pathological and bacteriological tuberculosis. Bacteriologists regard everything as tuberculous in which tuberculous bacilli are found. When a section of a wart is put under the microscope and a bacillus is found they take it for granted that there must be millions behind and call it tuberculous, whilst I call only those things tuberculous which are composed of cells—organisms grown out of the body. Tuberculous bacilli alone do not constitute tuberculosis.” There will be the Koryphæ of scientists at that Commission working together to find a sure basis for therapeutics. Koch's labours are not lost to mankind. Whether the bacillus alone or in conjunction with Virchow's pathological cell or by their discovery of a new ingredient in tuberculosis they are sure to arrive at it at last. Lister commenced his labours with carbolic patty, spray, and faith. He developed his system gradually and patiently until now, when Lord Lister is considered the greatest benefactor of suffering humanity by all nations. Nowadays we are in too great a hurry for immediate cures.

## Budapest.

[FROM DR. ADOLF EEDÖS.]

August 20th, 1901.

At the recent meeting of the Nagyvárad Medical and Pharmacological Society, Dr. Révész, Vilmos, demonstrated a pathological preparation originating from a patient who had suffered from

### SPINAL AFFECTION.

The patient, æt. 36, was admitted to the hospital on August 6th, 1900. He complained that he had previously been very weak, and he was therefore unable to walk. His condition subsequently improved, but at the beginning of 1901 he again became gradually weaker, and since May had been confined to bed, having neither strength nor wish to sit up nor to get up, and in his lumbar region he complained of marked numbness. Along the spinal cord there was slight pain on pressure; tactile sensibility was diminished below the first thoracic vertebra from the level of the nipple, and there was total analgesia involving the lower extremities. He did not feel a pin prick, but after some delay he noticed pressure with a finger. Cutaneous sensation, *i. e.*, tactile sensibility, was wanting over both knees and over the lower third of the thighs. The heat-sense, too, was greatly reduced; he mistook at the outset the sensation of heat and cold, and he noticed more gradually the change from cold to warmth.

On the upper part of the trunk and over the limbs the tactile heat and pain sensations were normal. Knee reflexes were increased; in the muscles were seen fibrillar twitchings. On the lower part of the right leg the muscles became atrophied, and he alleges the malleolar joint has since his childhood been always rigid. The left lower extremity is not atrophied; on both limbs passive movements give rise to spasmodic contractions. There was no disturbance of the functions of the bladder

or rectum. In the course of the later months serious contractions presented themselves in the lower limbs, besides obstinate constipation and bladder symptoms. At the height of the nipple severe zozary pains; on the trochanters were seen the effects of decubitus. Under the whole course of observation no alteration occurred in the thoracic organs, but only a tickling cough, with moderate expectoration of a catarrhal character.

The autopsy showed the following: When the spinal canal was opened, the dura mater was deeply bathed in pus in the region of the fourth and fifth ribs, which passed through the adjacent intervertebral openings into the thoracic cavity, communicating with the latter. The openings were covered with caseous masses, which were already softened and decomposed. The dura mater of the cord was greatly thickened at this place; it was very hyperæmic, and was infiltrated with tuberculous material. The spinal cord, owing to compression, had become flattened, pale, and anæmic, and when cut across the margins of the medulla spinalis turned outwards. The right lung was firmly adherent to the parietal pleura; when separating it a large cavity was seen extending over all the three lobes which communicated through the intervertebral openings with the spinal canal. The anterior surface of the lung was sound, with emphysematous isles; the left lung was found to be quite healthy. On the ground of these conditions the author was justified in supposing that he had to deal with a primary pachymeningitis externa, the cause of which was tuberculous caries of the vertebrae. The myelitis was of secondary occurrence. The pus passing towards the thoracic cavity caused the decomposing process in the right lung.

It is yet a matter of question to decide whether the pachymeningitis externa may be a primary or a secondary disease. In most cases it is a secondary factor, but in the present case he had no doubt that it was of primary occurrence. This is proved by the fact that neither on the admission of the patient to the hospital nor later on did the signs of more severe alterations in the lungs show themselves. The slow process commenced between the narrow walls of the spinal canal, broke through from thence the intervertebral opening, and penetrated first to the thoracic cavity, then into the firmly adherent lungs. Traube also found that in similar cases the primary disease was the pachymeningitis externa, which subsequently extended into the dorsal muscles.

At the time of the patient's admission the diagnosis of Dr. Révész was syringomyelia, on the ground of several symptoms, and even the further progress of the case seemed to strengthen this diagnosis. However, the autopsy failed to authenticate it.

#### SARCOMA OF THE CHOROID.

Dr. Waldmann, Bèla, brought forward a patient whose disease he calls sarcoma choroideæ.

The patient, a man, æt. 24, about eight weeks before noticed that he did not see absolutely with his right eye. On examining the eye Dr. Waldmann found the cornea intact, and also the conjunctiva, but the anterior chamber was deeper than normal. The conjunctiva was injected in one place only. By focal lighting he noticed at one part of the pupil a brownish-red growth, and when the light had been thrown on this spot there

appeared a reflection. The other part of the pupil remained black.

The diseased eye will be enucleated, and after performing this operation Dr. Waldmann will demonstrate the preparation of the pathological eye, and he will again return to this subject.

Dr. Edelmann, Menyhert, read a paper on

#### MELÆNA NEONATORUM.

The patient was a baby, five days old, well built, and seemingly quite healthy. On the day when first seen it vomited after having been suckled, and the vomited milk was mixed with blood. This repeatedly occurred on the same day, and the infant sometimes brought up mere blood, the colour of which was bright red. The faces were dark-coloured from the altered blood in the bowels. On the following day, i.e., on the sixth day of the baby's lifetime, Dr. Edelmann saw symptoms of trismus. From this cause the baby was unable to suckle, although it took food given in a spoon. Death occurred on this day.

In this case sudden bleeding had set in. The blood was derived from the stomach and from the bowel. This bleeding itself was really not a disease, but rather a partial symptom of a disease. The fundamental malady must evidently have been some constitutional disease, as, for instance, syphilis, sepsis, hæmophilia. On the other hand it might also have been a local disease of the stomach or bowel arising either from trauma or from a disturbance of the circulation, for instance, by an ulcer or an erosion. This case may be put down to the first group although he could not elicit any further particulars from the parents of the child.

The interest of this case is in the fact that this disease is relatively very uncommon. Among 700-1,000 parturitions it occurred only in one case (Runge). The bleeding commences a few hours after delivery, most frequently on the second day, but rarely on the fourth or later days (in our case on the fifth day). Fifty to sixty per cent. of cases end fatally, mostly owing to the severe hæmorrhage.

## The Operating Theatres.

### GREAT NORTHERN HOSPITAL.

OPERATION FOR RENAL CALCULI.—Mr. PEYTON BEALE operated on a woman, æt. about 26, whose history was as follows: Ten years previously she had suffered from considerable pain in the left lumbar region and had passed blood in the urine at intervals; the pain had continued with greater or less severity till the present time, but no blood had been passed for at least six years. The patient was extremely spare, and had been admitted under the care of Dr. Beevor, who asked Mr. Beale to see her with a view of determining the nature of the pain. The abdomen was therefore carefully examined, at first without an anæsthetic, and both kidneys were easily felt, in fact every viscous in the abdomen could be quite easily made out, a circumstance which Mr. Beale said must be regarded as quite exceptional. Although each kidney was carefully examined no calculus could be felt, but the left kidney was distinctly larger than the right. On another occasion the abdomen was examined under an anæsthetic, but as the operating theatre was occupied at the time the examination was conducted in the ward, the patient

lying on a bed with a spring mattress. Under these circumstances no calculi could be detected, although the whole outline of the left kidney was easily made out. A few days later a skiagram of the abdomen was taken, and this showed two or three dark patches, each about the size of a filbert, occupying the position of the left kidney; no such dark patches were visible in the region of the right kidney. The patient then went out, but the pain in the left loin still persisted, so she was again admitted, and Mr. Beale determined to cut down upon and explore the left kidney. The patient was brought into the theatre, anaesthetised, and placed on the operating table, the surface of which consists of perforated zinc, *i.e.*, a hard, fairly level surface; upon palpating the left kidney the presence of numerous calculi in it was at once detected beyond all doubt, for they were felt grating against one another without the slightest difficulty. The kidney was then exposed from the loin, and about a dozen hard calculi of all shapes and sizes were easily removed with forceps and scoop. The wound in the kidney was sutured, and the edges of the incision in the loin were brought together, with the exception of a small portion at the lower extremity, about one inch in length, in which a gauze drain was placed. Mr. Beale said that there was a very interesting moral in this case, and that was never to examine the abdomen unless the patient was lying on a hard flat surface. In the present instance he had been obliged to examine the patient in bed on the first two occasions, and he had not been satisfied with the procedure, as he had before met with cases in which renal calculi were only detected on palpating the abdomen when the patient was lying on a hard flat table. The skiagram, he pointed out, was a help in that it showed some abnormality in the region of the left kidney, but the mass so shown was quite indistinct as regards shape. Even after the incision had healed up he expected the patient to return with a sinus at the seat of the wound through which urine would pass. He considered it advisable to remove the remains of the kidney at a subsequent operation, and not at the time the calculi were taken away, as if both were done at once shock was generally very severe, moreover, he thought that it was easier to make sure of removing the whole of the damaged kidney structure at a later date, because as the whole organ shrinks up its extent is more easily determined.

Urine came through the wound for about a week only subsequently to the operation, and the patient was discharged to a convalescent home three weeks later, the wound having quite healed.

**A Lady Dentist Fined.**

A PROSECUTION of some interest to the dental profession has just taken place in London. Two brothers, named Eskell-Paget, converted their business into a limited liability company. One of them withdrew and entered into a covenant not to practice within a certain radius of the original place of business. That condition he broke, and was restrained from carrying on practice by an interim injunction. His wife then carried on the business as the "Eskell-Paget Dental Company," and was summoned for unlawfully using a description implying that she was registered under the Dentists' Act and was qualified to practise dentistry. The magistrate convicted, and inflicted a fine of £5, with £3 3s. costs, with leave to carry the case to a higher court.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 28, 1901.

**THE DANGERS OF THE STREETS.**

THERE are certain aspects of social life to which the attention of the medical profession is specially drawn. Among them may be mentioned the death-toll of human lives that is annually exacted by vehicular accidents in the streets of the great towns of the United Kingdom. In London alone the number of persons thus killed mounts to the dimensions of a small army. Yet it may be doubted whether the citizens of that vast metropolis, busied as they are with multifarious and absorbing pursuits, realise with anything like exactitude the appalling extent of the mischief that is being done in their highways. The recent death of a prominent official has brought the subject prominently under public notice. In that particular case the cause of death was determined by a coroner's jury to have been purely accidental, but it may be hoped that the wider question thus raised, namely, the dangers of street traffic, may not be allowed to escape without full journalistic discussion. To a great extent the medical profession is concerned, for most of the cases of injury and death resulting from street accidents come under their notice as hospital residents, coroners, or private practitioners. Medical men are in a position to furnish a vast amount of evidence in this important matter, and to set forth in its true proportions a public danger which we venture to regard to no small extent as preventible. Danger to pedestrians may clearly arise from a variety of causes, which may be either due to their own acts, or to those of drivers, or to the instrumentality of pure accident. Personal defects of sight, hearing, or bodily health account for a certain number of street injuries. Recklessness on the part of foot passengers is, in many instances, the main contributing factor. Runaway horses have to be reckoned with, as well as collisions between vehicles and the modern developments of cycles and motor

cars have given rise to their own peculiar dangers. After allowing for the unavoidable margin of accidents, however, there remains a certain proportion due to the incompetence, carelessness, or recklessness of drivers. The police have done their best by a system of registration to regulate those in charge of vehicles, but it may be doubted if offences on the part of licensees are not too readily condoned by restoration of the badge. The root of the evil appears to be a fixed belief on the part of drivers that the road belongs to them, and that all they have to do is to shout to a pedestrian without attempting to stop. In a great majority of vehicle accidents to wayfarers, we believe that the mishap has been brought about by the absurd theory in question. It has been pointed out by a judge that drivers were mistaken in holding that opinion, and that the foot passenger has an equal right to the roadway as well as to the footway. We firmly believe that a vast bettering of the conditions of street traffic could be quickly secured if magistrates and coroners would insist upon the rights of pedestrians in all cases of injury or death from street vehicles brought under their official notice. The police, also, would be able to bring a great deal of pressure upon drivers by way of inducing them to recognise the real law of the road. New dangers are being added to the streets by the development of cycle and motor car and tramway traffic. These facts are being constantly impressed upon medical men, not only on account of accidents, but because they themselves travel upon the King's highway more perhaps than any other section of the community. As regards both cycles and motor cars there can be little doubt that they should be legibly numbered, and that in case of an accident the police should have the power of detaining the owner until his identification has been established. As things go the rider or driver may knock down and maim, or even kill a pedestrian, and, by giving a false name and address evade further responsibility. That state of things amounts to nothing short of a public scandal and its amendment claims early legislative attention. Meanwhile it is a matter of philosophic interest to note how the increase of material prosperity swells the figures of the annual mortality from street accidents. At the same time it is clearly the duty of those responsible for the safety of His Majesty's lieges to see that the loss of life and limb from that source be reduced to the lowest limit of the unavoidable margin.

#### HOSPITAL ABUSE.

THE Forty-third Report of the Board of Superintendence of Dublin Hospitals for the year 1900-1901 has just been issued as a Parliamentary Blue Book. Among many important and interesting details of, and comments on, hospital management generally, one comment seems to us worthy of special attention, inasmuch as it touches upon a matter of extreme practical importance. "Whilst we recognise that under

existing circumstances it is not possible to exclude patients who are not, in a financial sense, legitimate objects of charity, we feel that discrimination should be exercised to ensure that the funds provided for charitable relief should not be spent on persons who are competent to pay for such advantages." The question how to prevent the abuse of hospital charity is one which presses for an answer, which is most difficult to answer, and which at the same time has been most persistently neglected by those whose duty it is to find a suitable answer, viz., hospital boards. The latter bodies are elected to administer the funds of an institution—funds which have been provided by a charitable but careless public for a definite object. In the administration of these funds, the guiding principles should be efficiently to relieve the greatest amount of suffering with the maximum amount of economy that efficiency will permit, and to see that funds collected in the name of charity are expended in the furtherance of charity. All hospital boards, we believe, fully recognise the first of these propositions—a principle important and true if followed in such a manner that the second principle is not at the same time abandoned. Unfortunately, there is a widespread tendency to consider that the first principle stands pre-eminent, that it is the only principle to be followed in the management of a hospital, and that the amount of support which a hospital deserves is in proportion to the number of patients which it relieves. We doubt if a hospital governor ever asks himself or his colleagues whether the long list of many hundreds or thousands of patients relieved in the course of a year represents the same number of necessitous persons treated by charity for the sake of charity, or whether it does not represent a large proportion of charity expended on persons who are not fit recipients of charity. Hospital governors, if taxed with the indiscriminate bestowal of hospital relief, answer that they have opened pay wards into which such patients as can afford to pay are admitted. This is true. but what does it mean? It means that the governors have shifted the responsibility for the bestowal of charity from themselves on to the medical staff. That, in other words, they have said to the patient "You are not an object for charitable assistance, you must pay for your board and lodging, my servants—the medical staff—will then bestow their charity upon you, and prescribe for you, or operate upon you free of charge." And the medical staff, by the rules of the hospital, are compelled to do so. "If they do not," says the Board, "there are other medical men anxious to do so in order to obtain opportunities for gaining experience." We do not want to convey that hospital boards act thus out of mere disregard for the interests of the staff, or out of carelessness in the discharge of their duties. There are few hospital governors who act from either of these motives. The real difficulty in the way of reform is that the governors are, in most cases, men whose time is fully occupied by their private duties, and who have not got the necessary

leisure to devote to the solving of the problem of hospital abuse. Moreover, hospital governors do not, as a class, appreciate the harm which is done by the injudicious bestowal of charity, or the injustice and hardship which such a bestowal inflicts on struggling general practitioners. If they appreciated these points we believe that reform would follow. If a body of men undertake the disposal of funds which have been collected for the relief of the necessitous, it is their direct duty to ascertain that these funds are not used for the relief of the fraudulent. If this end cannot be obtained by indirect means, such as the posting up of notices intimating those who are eligible for the relief afforded by the hospital, the authorisation of the medical staff to refrain from treating patients who are manifestly unsuited for hospital relief, &c., it should be obtained by the direct means of appointing an official to inquire into the circumstances of new patients. This is not the difficult or impossible task that it is usually represented to be. Much can be done to effect reform by the mere process of keeping a book in which the name of the patient, occupation, abode, wages, number of children, and so forth are entered. Such a book will readily show cases which are manifestly subjects for charitable assistance, cases which are manifestly not subjects for charitable assistance, and those which are doubtful. If there is any doubt as to the *status* of a patient, it should be the duty of a special official to make further inquiry. Some patients will undoubtedly tell falsehoods. The number will not be great, and after a few have been detected the number will be still smaller. It may be said that little good would result from such a course. With this opinion we do not agree. At present nothing is done, with the result that the out-patient departments of hospitals are thronged with patients who are unsuited for medical charitable relief, who come there believing, or affecting to believe, that they are entitled to receive it, and who are grossly insulted if they are regarded as recipients of charity. Some solution must be found for the problem of hospital abuse. It is unfair in the extreme, in fact it is immoral, to compel a medical man to perform acts in his public capacity of hospital physician or surgeon which he would not perform in his private capacity - acts which have the effect of depriving of the means of livelihood a possibly necessitous professional brother. And when all circumstances are taken into account, what else do the boards of many hospitals compel their staff to do?

#### NAPHTHALINE POISONING?

IN the first two decades of the Nineteenth Century the name "aromatic compounds" was given to a small group of naturally occurring bodies possessing an aromatic smell and taste. For in those days the physical properties and not the chemical composition guided the nomenclature. It fortunately happened that the name was suitable, for it was found that in addition to certain analogies in their outward properties they were connected by close

chemical ties. In 1832 Liebig and Wohler's paper on the radical of benzoic acid, benzoyl, appeared. The discoveries of other bases soon followed. Berthelot found that if acetylene be heated to a temperature sufficiently high a considerable quantity of benzene is produced. At the same time styrolene, naphthalene, and other hydrocarbons are produced. In 1838 Pelletier and Walker drew attention to the opportunities afforded in preparing trade chemicals for studying new bodies. The by-products of coal-gas yielded naphthalene to Kidd. In 1873 Markownikow and Pylobin found a peculiar group of hydrocarbons in Caucasian petroleum, to which they gave the name of naphthenes. Naphthalene is now obtained almost altogether from crude petroleum, distilling over at a temperature ranging between 180 degs. to 220 degs., from which it crystallises on cooling. It forms colourless, shining, leafy crystals of peculiar odour and burning taste. It dissolves readily in alcohol, ether, chloroform, carbon disulphide, benzene, and fixed and volatile oils. From Cohn's physiological experiments, in 1894, it was considered that the chemical was completely destroyed in the body of dogs, and from the known properties of the drug it was recommended as a vermicide in cases of tape-worm, the dose being twenty grains dissolved in castor oil. In such doses, though often repeated for days, no toxic effects were produced. As an ointment it has been applied in the proportion of one part in eight without even producing a rash; withal even pure naphthalene has been known to produce toxic effects. Rossboch's patient suffered from cyanosis of the lips and cheeks, twitching of the muscles, and black-coloured urine from taking ninety grains; it has also produced strangury, and in at least one case its external use was followed by toxic symptoms. In 1896 it was, however, replaced by naphthalour, of similar chemical composition, though differing greatly in its physical characteristics. It is said to be harmless, and is recommended for all forms of skin diseases, burns, ulcers, and even rheumatic pains. A solution of one of these chemicals was recently used by a Mr. Mallan, of Dublin, in the preparation of a non-poisonous sheep-dip or disinfectant. To show that the compound was not poisonous the deceased was in the habit of drinking some of it. Probably the solution was prepared with methyl alcohol; be that as it may, the unfortunate man drank a quantity of the mixture and died from the effects a short time since, and a coroner's jury found a verdict in accordance with the evidence. There was no necropsy, neither was there any report of the symptoms from which the man suffered, nor any chemical examination of the contents of the stomach. The medical attendant was not to blame for not giving the symptoms, for he was not called in until some fifteen hours had elapsed from the time of swallowing the disinfectant. We incline to the view that the death resulted from the agents used to dissolve the naphthalene, and not from the hydro-carbon itself. And we regret that no post-

mortem was ordered. It would have been interesting to know the condition of the mucous membrane of the alimentary canal and of the urinary apparatus; nor can we understand why an analysis of the contents of the stomach was not made. There is no suspicion of foul play, but the circumstances called for an analysis if only to ascertain the cause of death, a function of the coroner's court that does not a little to safeguard the lives of His Majesty's lieges.

### Notes on Current Topics.

#### Suicide at a Kent County Asylum.

AN inquest was held last week upon the body of an inmate of Barming Asylum, Kent, when it was proved that deceased committed suicide by hanging. The evidence revealed the fact that there was only one attendant in charge of a ward in which were forty-four patients, several of them with suicidal tendencies. The jury expressed an opinion that there should be at least two attendants in the ward. If the state of affairs be as alleged there can be little doubt that a most serious flaw has been disclosed in the administration of the institution in question. Barming Heath Asylum, it may be said, is the larger of the two county asylums of Kent, and has some 1,638 beds. An explanation may be forthcoming for leaving the ward to the care of a single attendant, perhaps on the score of the sudden illness or holiday absence of the staff. In any case, however, provision should be made for emergencies of the kind. It is hardly credible that a county asylum of first magnitude should entrust a ward with "forty-four patients, some of them suicidal," to the care of one man. The Lunacy Commissioners will doubtless hold an exhaustive inquiry into the matter, and may be confidently expected to make any administrative changes that may be necessary to the future safeguarding of the inmates of the Barming Heath Asylum.

#### Verminous Police Cells.

PUBLIC attention has been called to the existence of swarms of parasites in one of the London gaols. In several instances prisoners under remand have obtained bail on the ground that life in the prison was a prolonged torture on account of the vermin with which the cells were infested. There seems to have been no attempt on the part of the gaol officials to contradict the assertion of what constitutes an exceeding grave defect in administration. There can be no excuse for the existence of such a state of affairs, for clearly prison cells can be kept absolutely free of vermin by a proper system of cleanliness in combination with such modern sanitary measures as disinfection and the use of antiseptics. The police exact a high standard in the case of common lodging-houses, and prosecute the owners when vermin are found in the beds. Is it any more difficult to keep a police cell clean than the room of a lodging-house? Of the

two most people would say the chances were greatly in favour of the police cell, with its special construction, its absence of overcrowding, and the official service and capital at command. The fact is that the whole of our prison system wants overhauling from one end to the other. A commission of inquiry should have medical and sanitary experts who would consider every item of environment, food, clothing, exercise, sanitary and personal cleanliness, and all other things from a scientific and humanitarian point of view. The treatment of many persons locked up for the night in police cells demands minute inquiry as to the warmth of cell, coverings of prisoner, food given, and supervision exercised. In some instances the treatment of prisoners locked up from Saturday to Monday in the way of food and exposure is enough to bring on serious physical disease, that is to say, if the report of some of these unfortunate persons on coming to hospital later in the day may be believed.

#### Broken Ribs Overlooked in Hospital.

A CURIOUS incident was revealed at a London inquest last week. A woman slipped on the pavement one night and fell against the handle of a costermonger's barrow. Three days later she applied for medical assistance at the Western General Dispensary, where, it was stated in evidence, she said she had a sore throat and had fallen and injured herself. Her chest, however, was not examined, and next day she went to St. Mary's Hospital, where she was treated by the house surgeon for "laryngitis." Two days after the last visit a private practitioner who was called to deceased found her suffering from pneumonia, the result of five fractured ribs on the left side. She died from syncope on the following day. The jury expressed an opinion that a more careful examination of the patient would have revealed the existence of the fractured ribs. The history of a blow would naturally lead a medical man to examine the chest carefully, but it is only fair to say that the physician at the Dispensary denies that the deceased complained of anything beyond the sore throat. The Coroner, Dr. Danford Thomas, very properly pointed out that in a case of the kind it was essential to bandage the chest. The fact is to be regretted that so serious an injury should have escaped detection by the medical officers of two London medical charities. An occurrence of this nature suggests the need of a revision of administrative methods.

#### The Chigoe.

SIR HENRY COLVILLE tells a tale of a man who was tried before him on the charge of murdering his wife. The prisoner fully admitted his guilt, but explained the killing of the unfortunate woman by stating she was infested with the chigoe. The chigoe, or jigger flea, causes cyst-like formations that can be seen immediately under the skin looking like little fibrous swellings as large as a pea. Their removal must be complete, otherwise an ulcer ensues

which may cause a considerable amount of distress. The native home of the chigoe is South America, but it appears to have been recently introduced into Africa, where, on the West Coast, its wonderful power of multiplying rapidly and travelling far has soon caused its presence to become a matter of comment. Emin Pasha's expedition is further credited with having spread this pest in the continent of Africa, and Sir Henry Colville, describing its progress in Uganda, says that it has maimed whole populations. He foresaw that the jigger would reach the Eastern coast, and it is probable that before long India and Arabia will be invaded by the insect. It is like a small flea in appearance, and curiously enough jumps in the same manner as the flea. It can live and breed in countless numbers in sandy soil. For an hour or two after it has made its way into the skin of the foot no particular irritation is felt, but in a short time excruciating pain is complained of, and the only means of obtaining relief is to promptly extract the intruder, and this must be done most efficaciously and thoroughly. According to Dr. Moffat, an important part of the work of missionaries at the present time consists in imparting to the natives the necessary knowledge of how to effect in a proper manner the removal of the chigoe when it has gained an entrance through the epidermis.

#### Prophylaxis of Blindness.

THE great frequency of ophthalmia neonatorum in Paris, and the frequency with which it is followed by loss of sight of one or both eyes, has latterly engaged the attention of the French Government. The initiative in the matter was taken by Senator Dr. Pedebidon, who brought before the Senate the desirability of asking the Academy of Medicine of Paris to issue instructions to the midwives of the districts of the city to bathe and daily wash the eyes of the newly-born children with a weak solution of permanganate of potassium. The Academy of Medicine recognising that they had no power to enforce compliance with their instructions to the midwives, suggested that the following rules be adopted by the executive:—(1) That there be distributed in each district, with the certificate of birth, a paper giving the causes, symptoms, and dangers of ophthalmia of the newly-born. (2) To ensure that all cases of the disease are duly notified by midwives and doctors. (3) That in all maternity hospitals, there shall be an ophthalmic surgeon, whose duty it shall be to treat the ophthalmia of the newly-born, and to instruct students and midwives in the treatment of the disease. These are admirable suggestions in their way, but is the last one necessary? From what we ourselves have seen of the disease, or perhaps it would be more correct to say from what we have not seen of the disease, it is well proven to our satisfaction that if the precautions and prophylactic treatment laid down by Crede are followed in maternity hospitals there will be no ophthalmia neonatorum. This mode of treatment is as simple as it is efficacious, and

though it may sound well to be able to say that an ophthalmic surgeon is attached to a maternity hospital, still there is more chance of good resulting to a greater number of infants if the regular officers of the hospital make it their business to instruct the charge nurses in their duty in these cases. It will thus be far more thoroughly brought home to the midwives that the prevention of ophthalmia presents no difficulties which they cannot overcome themselves.

#### Pathological Lying and Dreaming.

It is well-known that in hysteria a form of reverie may occur in which the patient imagines the dream in such a vivid and real manner that it henceforth becomes as a matter of fact to her. This morbid state may result in false witness being given, and the term "pathological lying" has been applied to it, Professor Pick, of Prague, has published a curious study of some patients under his care who suffered from day dreams which were so distinctly pathological in their character that the patients themselves recognised their psychiatric significance, and sought medical advice to rid themselves of the domination of a succession of dream pictures. The practical side of the question is shown in the incapacity of these patients to follow their usual vocations in consequence of these day-dreams causing a reaction in various ways, such as talking aloud and gesticulating. This is one of those studies of psychiatry which is liable to excite the ridicule of the thoughtless, but the practical effect of these day-dreams is by no means a laughing matter to the unfortunate sufferer.

#### Medical Advertising under the Pharaohs.

THE King Sahura, who lived 3,500 years before Christ, wished to record his gratitude to his doctor because he had "made his nostrils well," and for that purpose he caused an inscription to be engraved on a tablet in which he wished him long life and happiness. The inscription shows further that the King's physician appreciated the pecuniary benefits of publicity, for at the doctor's own suggestion to his royal master the tablet, or in plain English the advertisement, was placed in a conspicuous position in the waiting room of the regal palace, and it is to be hoped that the worthy practitioner reaped the benefit he deserved, not only for his successful treatment but also for his evident business capacity. Dr. J. Wright in the *Laryngoscope* has written an entertaining article on the subject, which those interested will do well to consult.

#### The Saddleworth System of Medical Relief.

THE Saddleworth Guardians have instituted a system by means of which poor persons can obtain medical relief from any doctor they may desire to consult residing in that neighbourhood. Mr. Colin Campbell, of Saddleworth, has explained the method fully in an article he has written in the organ of the Manchester Medical Guild, the *Medical Guild*

*Quarterly*, under the heading of "Parish Doctor and Outdoor Medical Relief." The method is simplicity itself: The Saddleworth Guardians appoint every registered practitioner in the district who may so wish to be a district medical officer, and in this manner the ordinary contract medical officer's work is avoided, and much unnecessary professional friction is done away with to the advantage alike of patients and practitioners.

#### Pruritus and Lymphadenoma.

THE connection of pruritus with lymphadenoma is not mentioned in the majority of our textbooks on medicine, but the fact that this complication is something more than a mere coincidence has been emphasised by Dr. W. Cottle and Dr. Lee Dickinson, in a communication published in a contemporary describing three cases of pruritus associated with lymphadenoma. The importance of the subject lies in the fact that pruritus in lymphadenoma is of serious prognostic import, and in instances which otherwise do not appear beyond recovery this complication, particularly if accompanied by pigmentation of the skin, is of grave significance. In the cases described the rapid course of the malady fully bore out the prognostic gravity of the pruritus.

#### The Parisian Medical School.

THE falling-off in the number of foreign students attending medical classes in Paris has incited the Municipal Council of the city to take steps to increase the facilities for medical teaching and make the school more attractive. In a series of articles in *L'Eclair*, M. Daussett, President of the Council, shows that during the past twenty years the French schools of medicine are being gradually deserted by foreign students, who now seek instruction in Vienna and Berlin. To stay this stream of foreigners from Berlin and direct them to Paris it is proposed that a "Municipal Institute of Practical Medicine" be established, and supported at the expense of the city. In the institute the student will see the practical application of the theories he has learned in the lecture room. Wards containing about twenty beds each will be utilised for clinical instruction. Each ward will be devoted to a specialty, and be under the care of a specialist who has attained distinction in his branch of medicine. Post-graduate lectures and clinical instruction will be delivered, and it is hoped that many practitioners will avail themselves of a four or six weeks' course every year for the first five years of their professional life. Patients are eligible from all parts of French territory, the desire being to secure specimens of the pathological states that call for careful investigation either from their pathology being little known or from their not being amenable to treatment. We heartily wish the scheme success; the home of Pasteur should be an attraction to students, and our French *confreres* are well advised in teaching Pasteur's theories and demonstrating his teaching in Paris and not relegating the duty to German professors in Berlin.

#### Veratrum Viride in Puerperal Eclampsia.

ANY drug which can be proved to have influence over this serious malady is worthy of note. According to the *Clinical Review* of July, 1901, "at the late meeting of the American Medical Association a number of speakers firmly held to the conviction of the superior efficacy of veratrum viride in puerperal convulsions in comparison with any other drug we possess. While in the convulsion chloroform, of course, would give a rest and relief to be procured in no other manner. Beattie, of Kansas City, recommended that the veratrum be given in ten minim doses, hypodermically, to keep the pulse low. Confield, of Cincinnati, held that in full-blooded persons with a high pulse veratrum could be said to be quite a specific. He advised that from fifteen to sixty minims of Norwood's tincture (according to the patient) be given every fifteen minutes until the pulse reached sixty, where it should be held for several days. In thin anæmic patients with small pulse this drug should not be used. Chloral and morphine were the agents to employ in such instances."

#### The Treatment of Goitre.

AT the last annual meeting of the German Surgical Society Professor Kocher presented the following statistics of his treatment of 1,000 goitres by operation. Of these 929 were cases of simple glandular enlargement, of these four died; twenty-seven were cases of malignant growth, of which six died; twenty cases were of an inflammatory character, of which but two died; twenty-four were cases of exophthalmic goitre, of which two died. These statistics are not alone valuable from their number, the care with which the cases were registered greatly enhances their value: thus we find that of cases of simple growth of the gland, in four cases the growth returned and he had to enucleate the gland. As a rule he found it sufficient in simple enlargements to excise such portions of the gland as were interfering with respiration. His most troublesome cases were those of proptosis; the extirpation was both troublesome and dangerous. Such a brilliant record cannot fail to influence medical opinion. The older methods of blisters, setons, iodine painting, and so forth, were eminently unsatisfactory, and the thyroid extract treatment too often failed to produce the desired effects, and not unfrequently caused undesirable results.

#### The Antiseptic Duel.

A DUEL has lately taken place between the son of a celebrated novelist and a well-known journalist of Paris, in which it is reported that in the course of the encounter the tip of the sword of one of the combatants was observed to touch the ground. The duel was immediately interrupted, and under medical supervision the weapon was carefully and scientifically disinfected. It is gratifying to hear that in consequence of the extreme precautions observed a wound inflicted on one of the parties to the duel is proceeding satisfactorily, and it is probable that in

future any danger that may appertain to modern French duelling will be entirely obviated, to the great satisfaction of all concerned.

#### Able-bodied Soldiers.

THE announcement is made that Lord Kitchener has ordered home a number of the new yeomanry lately sent over sea to the strength of 16,000. The alleged reason is that hundreds of the men are suffering from complaints of physical disabilities that would have been detected by the most cursory medical examination, and many of them are at present in hospital suffering from such diseases as varicocele, heart disease, deafness, lameness, and defective vision. As usual, the blame is thrown on the unfortunate Medical Department, which appears to be the favoured scape-goat of our chivalrous combatants. It must be clear as daylight to the man in the street that an unusual demand for soldiers means a lowering of physical standards. In the piping times of peace it is possible to pick and choose, so that the regular Army is supplied by recruits who, from a bodily point of view, are fittest of the fit. The demand for troops at the Cape is still unslaked, and it is to be hoped that the medical inspectors at home will resist pressure in future and weed out remorselessly all men who are unlikely to withstand the rough-and-tumble of an arduous campaign. Readers of the casualty lists must have noted the number of soldiers who are reported to have succumbed to heart disease and phthisis, which in a certain proportion of cases must have existed previously to their joining the Service. It is a question whether moderate errors of eyesight should be held a disqualification, for in the German and some other Continental armies the class of men labouring under this defect is found useful enough.

#### A Lay Indictment of the General Medical Council.

IN our correspondence columns will be found a communication from a medical man, commenting somewhat severely upon a letter from Colonel le Poer Trench, published in the *Times* of August 20th. The gallant gentleman in question made a frontal attack upon the General Medical Council on the ground that they were created for the protection of the public against unqualified practice, and "not to prevent research and new departures in medicine by qualified practitioners." The Council certainly do not adopt the first proposition, for they decline to prosecute unqualified practitioners, and assert that their function is purely to maintain certain ethical and educational standards among registered and duly qualified medical men. It was in accordance with that interpretation of their administrative powers that they took proceedings against the gentlemen who are mentioned by Colonel Trench, namely, Dr. Irvine, Mr. R. M. Theobald, and Dr. Alabone. Of these three the first, Dr. Irvine, capitulated upon an ethical matter. Mr. Theobald was struck off the *Register* for his connection with a notorious quack, Count Mattei, whose costly remedies

were shown by chemical analysis to have been simply water. Dr. Alabone was proceeded against for treating consumption by methods the worthlessness of which was fully exposed not only in the medical but also in the public Press. His advertised nostrum—"Lachnanthes"—is accepted by the Colonel as a Heaven-sent specific for the cure of consumption, apparently on the strength of a single case which improved between March and May. It may be remarked that any medical man who finds a cure for a disease and endeavours to make money by selling his discovery is running counter to the sound traditions of a noble profession. As to the suppression of quack practice by the Council, it has long been the earnest desire of medical men throughout the kingdom that the Council would undertake that most desirable task, or, if their powers were inadequate, that they would take steps to secure the necessary amending legislation. The second point of the gallant Colonel's indictment—namely, that the Council attempt to prevent research and new departures by qualified practitioners—is too absurd to need discussion in the columns of a medical journal. Legitimate scientific work is outside their control and their action in the case of Theobald and Alabone was directed against pseudo-scientific or quack methods foisted upon the public in ways contrary to professional usage—in other words, both matter and manner were illegitimate.

#### Ordnance Maps and Medical Men.

TO the country practitioner of medicine good local maps are essential, and it is somewhat doubtful whether, as a general rule, he is fully alive to the advantages of the Ordnance Survey maps. The recent change from a four-mile to the inch to a one-mile to the inch scale has greatly enhanced the value of these charts. For the small sum of one shilling a minute key to a district can be obtained, with full details as to villages, roads, canals, streams, houses, and a host of other physical facts. The cost of the map is only one shilling, so that the Government have not hindered the sale of their valuable production by burdening it with an excessive price. For all that, the sale of their publication is of a most meagre description. The inwardness of that curious state of affairs appears to lie in the complicated methods of sale which the Treasury have imposed upon the sale of the Ordnance map. The apparently simple plan of selling through the agency of local post-offices is so muddled and mismanaged that the intending purchaser finds himself faced with a quite unnecessary amount of formality, delay, and additional cost. In spite of these drawbacks, however, provincial medical practitioners may nevertheless be advised to turn to the Ordnance maps for accurate and trustworthy topical charts.

A SERIOUS outbreak of typhoid fever has occurred in Wales at Ebbwvale. Several deaths have resulted. There is no isolation hospital, and medical men are experiencing much difficulty in treating the patient

### Infantile Pneumonia.

ALL physicians dealing with infantile diseases have recognised the difficulty of diagnosing pneumonia in the early years of childhood. We need not repeat for our readers the symptoms of the disease or tell how prone the disease is to be overlooked until too late, or enumerate the diseases for which it may be mistaken; such information is to be found in every good text-book on infantile diseases. Unfortunately students are taught nothing of infantile troubles, and the young practitioner soon finds how insufficient has been his training when he comes to attend children. It is a revelation to him to learn that a child may die of pneumonia without showing any of the symptoms of the disease that he is so familiar with in the adult patient. Even to those familiar with the diseases of early life the recognition of pneumonia is not always easy, and the profession should be grateful to M. Weiss, of Lyons, who describes a sign of the disease in infancy which he has been acquainted with for months past. He finds that there is deficient expansion of the infra-clavicular region of the affected side. From his account the sign is pathognomonic. He has sought for it in other thoracic troubles in vain. It is not to be confounded with the want of expansion of the whole side, which is found in pleurisy and pneumothorax. The pneumonic sign is limited to the infra-clavicular space, and with it is found somewhat less than normal expansion over the site of the lesion. What adds to the value of the sign is the fact that it appears at the beginning of the attack, being well marked before the fifth day. To get the sign clearly it is recommended to strip the little patient and place him on the broad of his back, and when the excitement of the child at being undressed has passed off and the breathing has become normal the difference in the movements on the right and left side of the thorax will be readily seen. Care must, however, be taken not to confound the elevation of the clavicle with pulmonary expansion. The differential diagnosis between meningitis, typhoid fever, and influenza from pneumonia is greatly facilitated by this sign. It is also of much value in recognising the onset of pneumonia in children worn out with the wracking cough of pertussis—a danger not unfrequently unnoticed until the impending death calls attention to it. Considering that every general practitioner of medicine numbers many children among his clients, it is an amazing fact that the medical student is taught nothing of children's diseases, and gets his qualification without being asked one question on the subject.

### Coroners and Post-mortem Examinations.

THE lady resident of a London hospital, Dr. Louisa Garrett Anderson, gave evidence at an inquest held last week upon the body of a child that was brought to the institution dead. She stated that the child was obviously dead, and having ascertained that fact she had not examined the body further. Later it transpired that she expected to have been called upon to make a post-mortem exam-

ination. This drew from the coroner the remark that it was usual for a hospital doctor to examine a body under such circumstances to see whether there were any marks of violence. Where the cause of death was obvious an autopsy was not ordered unless subsequent criminal proceedings were likely to be taken. The matter evidently rests with the discretion of the coroner, who has in turn to depend on the results of the inquiries of his subordinate officer. While the holding of unnecessary inquests is to be deprecated on various grounds, it may be open to question whether post-mortem examinations might not be held more frequently to the public advantage. The consideration of criminal negligence sometimes crops up unexpectedly in the course of an inquest. So far as hospital residents are concerned, they are expected in the majority of cases to perform an autopsy, for which no fee is paid. On the other hand, they receive fees for evidence when a body is brought dead to the hospital, and a further fee for a post-mortem under those circumstances would be a small recompense for much gratuitous work.

### Low-flash Oil.

THE fame of Napoleon Bonaparte as a great military genius was founded on the lives of millions of his fellow-creatures. If one were to seek latter-day parallels in civil life they would probably be found amongst the millionaires who have amassed their money from industrial sources. The brewing trade will at once occur to many readers as an instance of a lucrative trade that brings misery in its train. At the same time it must be admitted that the brewers as a rule furnish good liquor to consumers. It is quite another matter, however, when an inferior and dangerous commodity is supplied to the public simply and solely because of its cheapness. That is the case of low-flash oil, out of which the fortune of at least one American multi-millionaire has been delved. Mr. Balfour's Government, in their wisdom, fixed the flash-point at 73 degrees, whereas the London County Council held that the minimum should be at least 100 degrees. This difference, formally sanctioned by the Legislature of the United Kingdom, helps to enrich American oil-trusts at the cost of the lives and property of English consumers. Statistics show that last year twenty-three lives were lost in London alone through the use of low-flash oil, while during the period from July, 1890, to March, 1900, there occurred from the same cause 2,055 accidents, of which no less than 250 were fatal. The whole question demands instant attention at the hands of any Government solicitous of the safety of His Majesty's subjects.

### The Abuse of Out-patient Departments.

WHENEVER any unfortunate oversight of hospital administration takes place a cry of horror is at once raised by a certain section of the public Press. No one can say that the administration of the medical charities is free from many a serious flaw and abuse, but, on the other hand, it may reasonably be urged that, considering the vast amount of good that is

affected, there is a wonderfully small margin of serious blunder. But there are two sides to every question, and in the present case the public have themselves to thank for many of the evils of which they so bitterly complain. Overcrowding lies at the bottom of ninety-nine out of every hundred of those unfortunate incidents that figure in the newspapers under the heading of "Another Hospital Scandal." Attendants, nurses, house surgeons, and medical staff find themselves swamped day after day with an endless array of work. The out-patient rooms contain scores of patients who ought to be under the care of private practitioners. Every morning hundreds and hundreds of patients from the suburbs and neighbouring county pour into the general hospitals of any great town, where, as often as not, they are treated by junior house surgeons or by students. Then, again, many a well-to-do person who is treated at a hospital for some surgical accident, returns thither for the whole course of treatment instead of going to a private medical attendant. Abuses of this kind it is clearly within the power of the public to control. Some day, no doubt, the out-patient departments of hospitals will be rigidly reserved for their proper duty, namely, to relieve the medical necessities of the poor.

#### PERSONAL.

**SURGEON-GENERAL W. TAYLOR, M.D., C.B.**, whose appointment to the Headquarters' Staff in London we referred to in our last issue, has now been appointed an honorary Physician to the King.

**THE Liverpool School of Tropical Medicine** learns that Major Ross is returning temporarily to England from Sierra Leone to arrange for the despatch of an expedition, similar to that now under his charge, to the Gambia and Gold Coast.

A **MASSIVE** and handsome marble fountain was unveiled last week at Saddleworth to the memory of the late Dr. Ramsden, who had resided at Saddleworth for thirty-six years. This fountain was erected by the public in token of their profound respect.

**LIEUT.-COLONEL F. W. TREVOR, M.B.**, Royal Army Medical Corps, has been gazetted to the local rank of Colonel in South Africa whilst Principal Medical Officer of a Division, and the following officers of the R.A.M. Corps to the local rank of Colonel in South Africa whilst Principal Medical Officers of General Hospitals:—Lieut.-Cols. J. L. Hall, G. H. Sylvester, G. E. Twiss, and F. A. B. Daly, M.B.

**THE grant of the local rank of Colonel in South Africa** made to the undermentioned officers of the R.A.M. Corps is continued to them whilst holding special appointments.—Lieut.-Colonel J. D. Edge, M.D., Principal Medical Officer Johannesburg District; Lieut.-Colonel J. A. Gormley, M.D., whilst Principal Medical Officer of a General Hospital; Lieut.-Colonel J. C. Dorman, M.B., whilst Principal Medical Officer, Eastern Line, Transvaal; Lieut.-Colonel A. T. Sloggett, C.M.G., whilst Principal Medical Officer of a General Hospital.

**THE will of the late Dr. McKim, Kelvingrove Street, Glasgow, has just been proved at over £22,000.** Dr. McKim was a bachelor, and died quite recently at an extreme old age. He had retired from the active duties of his profession for a number of years. He was a typical Highlander, and his practice was largely among the Highland people of the city, by whom he was much esteemed and his memory is greatly revered. Although possessed of ample means he lived a quiet and unpretentious, but, at the same time, a very useful life.

#### Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

#### THE PROPOSED BRITISH AND COLONIAL JOURNAL OF OBSTETRICS AND GYNÆCOLOGY.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

**SIR.**—It is quite unnecessary to reply in detail to the plausible, if somewhat prolix, letter of Dr. Sinclair, which appeared in your issue of the 14th inst. His natural desire to be the originator of what he hopes will be regarded as an "Imperial Journal of Obstetrics and Gynæcology" would obviously find expression in the steps which he took to bring his "venture" to a successful issue, and found a journal which should be in the future, as certainly it has been in its incipency, associated with his name.

It is obvious from Dr. Sinclair's account of the main obstacles to his project, that these were to be found in the "apathy" and "hostility" among "certain circles of London gynæcologists," and from "quarters" which evidently were not taken into consideration by Dr. Sinclair when he worked out his scheme, to which however, as he states in his letter, he found "many opponents" "entirely unexpected." Further, it is evident that he associates such opposition with the British Gynæcological Society, or at least with "its most influential members" residing in London, an opposition which he is kind enough to say is "highly creditable to their loyalty," referring, I assume, to their relation to their Society and their journal.

Now, Sir, this is exactly the point at issue, namely, Dr. Sinclair's ideas of "loyalty" to a Society of which he is a Fellow, and those of other fellows of the Society differently circumstanced to him, and who happen to take a different view of its interests and relations to other Societies. That his action was regarded at least with suspicion, is evident from the quotation Dr. Sinclair gives from one of its most respected and influential members, who "declined to move without fully understanding how the Gynæcological Society was likely to be affected."

There was a rumour, possibly not the outcome of "unconstrained conversation and gossip only," that the proposed journal was the first step towards the formation of a new Gynæcological Society, which would, in time, swamp the British Gynæcological. Will Dr. Sinclair say if he never contemplated the formation of such a society? If memory serves me rightly, I think he put forward such a scheme in a letter which he wrote to the *British Medical Journal*. How would the Fellows of the British Gynæcological Society regard their participation, under the cover of promoting the success of a journal, in a movement which might ultimately tend to the assassination of their Society? This would mean a little more to it than the starting of a rival journal!

Let me say plainly why "leading men in the Gynæcological Society resident in London rightly regard this movement with suspicion." I will put the reason briefly. Certain leaders of the Obstetrical Society of London, or, as they prefer to designate themselves, "the teachers of obstetrics" in London, have been, and are, the persistent antagonists of the Gynæcological Society, though a few of the more liberally-minded of them have not shown such animosity. The splendid

work done by the Gynæcological Society, and the distinction it has earned as the pioneer of modern gynæcological work in this country, may explain this. Its "Journal" is the standing record of that work. When, therefore, a proposition is made to start a new "Gynæcological Journal" it is most natural that the Fellows of the Gynæcological Society should inquire as to the relation that journal would hold to theirs, and further, how far the Fellows of their Society were invited to co-operate in view of what Dr. Sinclair terms "the unhappy differences among London gynæcologists." This "difference" every broad-minded man must deplore, and no one does so more than the writer.

When they find that they have been deliberately excluded, while the Obstetrical Society is largely represented, naturally they are inclined to hold aloof. And this is just what has happened. I saw the first printed invitation with the inviters' names, and with the exception of some few provincial Fellows (two from Ireland) there were no names on it of Fellows of the Gynæcological Society. Why was this, unless Dr. Sinclair had already concluded that the Fellows of the Gynæcological Society would regard his journal as inimical to the Society? Surely the proper way to have initiated a "Universal Imperial Journal" would have been to have had a truly "representative" meeting, summoned by as many of the leaders of one metropolitan society as the other, and to which the Fellows of the two leading societies should have been equally invited to attend. This would at once have shown the *bona fides* of the promoters, and have made the journal "representative of British gynæcology in the fullest sense." As this was not done, but a meeting held at which only "*friends of the scheme*" (the italics are mine) were allowed to be present, Dr. Sinclair will pardon the reiteration of my conviction that this journal has been "taken in hand mainly by those who are openly and avowedly hostile to the British Gynæcological Society and its journal," though I accept his avowal that there was no such hostility on his part intended in its conception. In conclusion, I would remind Dr. Sinclair that it does not follow that because the method of starting a journal is animadverted upon, that those who do so are necessarily its "opponents," nor in my previous letter did I assert or infer that the first meeting was a "*private*" one. I affirm that it was "one sided." This Dr. Sinclair himself admits. I certainly in no way "prophesied failure," but I did assert, and now repeat, that the method of launching the journal will prevent its being "in the truest sense representative of British obstetrics and gynæcology."

I am, Sir, yours truly,

A LONDON OBSTETRICIAN AND GYNÆCOLOGIST.

#### THE CONGRESS ON TUBERCULOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In *The Times* of to-day (August 20th) there appears under the above heading a remarkable letter from Col. W. Le Poer Trench. This letter is certain to give rise to a correspondence; and this, no doubt, will receive the editorial attention it may call for at the hands of THE MEDICAL PRESS AND CIRCULAR. My object in writing is simply to emphasise what I have more than once referred to in your columns, the fact that a vast amount of ignorance and prejudice exists in the minds of the educated public with regard to the medical profession. Col. Le Poer Trench may be taken as a fair sample of his class. His letter shows that he is not highly intellectual, and that he is completely ignorant of medical science; but he is intelligent enough to be a colonel in the Army, and wealthy enough to be able to offer a contribution of £1,000 towards a public test of "Dr." Alabone's "Lachnanthes" treatment of consumption. Colonel Le Poer Trench seriously believes that owing to prejudice or professional etiquette or trade union rules framed by the General Medical Council and observed by the profession, a great discovery has been practically kept from the public since the suspension of "Dr." Alabone fifteen years ago, "with the result that many thousands pronounced hopeless and incurable under the recognised treatments have been left to die." Colonel Trench's argument

amounts to this, that Dr. Alabone was unjustly expelled from the profession for infamous conduct, whilst, in fact, the whole profession has been engaged in an infamous and murderous conspiracy in withholding from their dying patients a remedy likely to save them and restore them to health. Colonel Trench has not taken the trouble to investigate even those questions involved upon which he is competent to form an opinion. Had he done this he would have learnt that no reputable medical man professes to hold and to purvey secret remedies; to do so constitutes infamous conduct. Every discovery, every advance in medical science, is made public; every supposed new remedy fully described so that it may be tested and tried by all inclined to do so. Tuberculosis causes 60,000 deaths annually in these islands; if anyone has discovered a drug or combination of drugs capable of curing this malady in any stage, let him make known the composition of his remedy, and if it stands the tests of science he need not fear that wealth and honour will not be showered upon him, not only in his own land, but in every country where tuberculosis claims an equal, or greater number of victims. Col. Trench's letter is a tissue of misconceptions from beginning to end; but these misconceptions could not have been entertained by anyone not grossly ignorant of the constitution of our profession, of its government, of its written and unwritten laws, and of the moral tone which characterises the bulk of its members and raises them far above the trades union level upon which Col. Trench places them.

I am, Sir, yours truly,

August 20th, 1901.

UBIQUE.

#### Obituary.

##### DR. A. LAWSON KELLY, OF GLASGOW.

WE regret to announce the sudden death of Dr. Adam Lawson Kelly, 26 Blythswood Square, Glasgow. He suffered from cardiac disease which necessitated him giving up professional work for over a year. His health had so much improved, however, that he sometime ago resumed work. A few days ago he was walking in Renfield Street when he was observed to fall by a policeman, who had him removed to the Central Railway Station, quite near. No professional skill was of any avail. Dr. Kelly, who was 65 years of age, was held in the very highest esteem by all with whom he was brought in contact, lay and professional friends alike. One of his sons is a medical man practising in the city. He has left a widow and grown up family to mourn their irreparable loss. The universal regard in which he was held makes his death to be very deeply deplored by all who knew him.

#### Medical News.

##### An Octogenarian's Violent Death.

AN inquest was recently held at Berwick on the body of Dr. David Cahill, aged over eighty, who was a graduate of Edinburgh University, and recently celebrated his jubilee as a medical practitioner. He died as the result of a fractured thigh, alleged to have been caused through his being assaulted and knocked down by Henry Gardiner, of the Cock and Lion Tavern, Berwick. After a four hours' sitting, the jury found that the doctor met his death by falling or being pushed down by Gardiner, but that the latter acted in self-defence as he had been struck with a stick by Dr. Cahill.

Dublin Death-rate.

THE deaths represent an annual rate of mortality of 20.6 in every 1,000 of the population for the week ending Saturday, August 17th. During the thirty-three weeks ending with Saturday last the death-rate averaged 27.2. It is interesting to note the beneficent effects on the mortality rate in Dublin of sunshine as the poor people in fine weather practically live in the streets, and the doors and windows of the fever dens of the city, euphemistically called unfurnished lodgings, are open to sunlight and fresh air. Uncertified deaths are still numerous. Ten such occurred during the week, and of

these eight were children, seven of whom were under one year of age.

**Failure of Water Supply.**

LEIGH-ON-SEA is unfortunate in the matter of its water supply. Twelve months ago the town was without water for no less a period than three weeks, an unpleasant experience that does not appear to have warned the local Council to set their house in order. Through another breakdown in the waterworks it is announced that the town is once again without water. The inconvenience caused by this failure is extreme, inasmuch as the place is full of visitors. The damage likely to be caused to a rising watering-place by recurrent water famines is obvious, and its full meaning is likely sooner or later to be brought home to the powers that be in the matter of the water supply of Leigh-on-Sea.

**Small-pox Outbreak in London.**

NUMEROUS cases of small-pox are being reported from various parts of London. During last week there were thirty-five patients under treatment for that disease in the hospital ships and wharf shelters of the Metropolitan Asylums Board, being an increase of twenty over the previous week. For several years London has been almost free of small-pox. The present outbreak will be watched with a good deal of interest because of the known hostility of some local governing bodies, notably that of Whitechapel, to vaccination, and also on account of the new generation of unvaccinated infants that is being yearly added to the population unprotected against small-pox by Mr. Balfour's Vaccination Act.

**The Mortality of Foreign Cities.**

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 83-60, Bombay 48, Madras 41, Paris 18, Brussels 16, Amsterdam 15, Copenhagen 14, Stockholm 15, Christiania 23, St. Petersburg 30, Moscow 30, Berlin 20, Hamburg 25, Breslau 81, Munich 20, Vienna 17, Prague 22, Buda-Pesth 19, Trieste 21, Venice 17, Cairo 38-43, Alexandria 33 38, New York (including Brooklyn) 24, Philadelphia 18.

**Pass Lists.**

**Royal Colleges of Physicians and Surgeons, London.**

THE following candidates passed the second examination of the board in anatomy and physiology at the recent quarterly meeting of the examiners:—

E. F. Rimington Alford and James Armstrong, of Univ. Coll., London; Berkeley N. Ash, St. Barts. Hosp.; Cecil K. Attlee, B.A.Camb., St. Thomas's Hosp.; J. Landells Blake and Frederick J. Borrie, Otago Univ. and Middlesex Hosp.; John H. Burridge, King's Coll., Lond.; Arthur H. Bond and Harold Clapham, St. Mary's Hosp.; William Byam and H. G. Shaokleford Courtney, St. George's Hosp.; Thomas C. A. Cleverton, London Hosp.; Robert H. Cotton, St. Thomas's Hosp.; Walter Crampton, Univ. Coll., Liverpool; A. Marcellus De Silva, Ceylon Med. Coll. and London Hosp.; W. Leonard Dickson, Middlesex Hosp.; Kenneth A. C. Doig, Westminster Hosp.; William S. Edmond, St. Barts. Hosp.; Evan E. Evans, Univ. Coll., Liverpool; Harry L. Evans and Charles B. B. Eyre, St. Thomas's Hosp.; Harry A. Fenton and Walter T. Finlayson, St. Mary's Hosp.; George E. O. Fenwick, Otago Univ., New Zealand, and Univ. Coll., Lond.; Harold N. Fink, B.A.Camb., and David H. Fraser, B.A.Camb., Camb. Univ.; William H. France, Westminster Hosp.; Edgar H. Geod, London Hosp.; G. Christopher Grundy, Yorks. Coll., Leeds; Percy Gully, Charing Cross Hosp.; Arthur L. Heiser and Daniel M. Humby, L.D.S.Eng., Middlesex Hosp.; George W. Heron, Westminster Hosp.; Cecil D. M. Holbrook, Hugh M. Huggins, and Algernon M. A. James, St. Barts. Hosp.; Thomas M. Hughes and William H. Kaye, Owens Coll., Manchester; A. Hilderbrand Jacob, London Hosp.; Henry H. Jenkins, Guy's Hosp.; Tikiri B. Kobbekaduwa, Ceylon Med. Coll. and Univ. Coll., London; Harold A. Kisch and George M. L. Lester, M.A.Oxon., St. Thomas's Hosp.; John E. Lascelles, St. Mary's Hosp.; St. Brown-

ing Lethbury, St. Barts. Hosp.; Frederick B. Lowe, William N. May, Percy F. Minett, C. Sculthorpe Morris, L.D.S.Eng., and Maurice J. Mottram, Guy's Hosp.; W. Cameron Macaulay, B.A.Lond., Middlesex Hosp.; J. C. Stuart McDougall, Otago Univ., New Zealand; Philip J. Marett, Westminster Hosp.; Aurelius V. Maybury, Durham Univ. and Guy's Hosp.; Roy C. Merryweather, Univ. Coll., Lond.; Echlin S. Molyneux and Idris N. Morgan, London Hosp.; Harold E. Moxon, St. Thomas's Hosp.; Alexander H. Muirhead, Francis M. Newton, and Charles W. O'Brien, St. Barts. Hosp.; Hamish Nicol, Westminster Hosp.; Gerald Nunn and Edward C. Peers, Guy's Hosp.; George B. Panton, London Hosp.; George A. Paulin, Royal College of Surgeons, Edinburgh; Christopher T. Fellow, St. Thomas's Hosp. and Cooke's School of Anatomy and Physiology; Alan F. C. Pollard and H. Hammond Rolfe, St. Barts. Hosp.; George H. Rains, Westminster Hosp.; Cecil E. Reynolds, Univ. Coll., Lond.; Cyril S. S. Rigby, Birmingham Univ.; Alexander Ruete, Univ. Coll., Liverpool; Griffith H. Rees, Gerald C. F. Robinson, Frederick Rogerson, Richard P. Rowlands, and Randolph St. G. Seagrove, Guy's Hosp.; Edward A. Smith, Univ. Coll., Liverpool; Edward J. R. Surrage, B.A., LL.B., and Cecil Vosper, King's Coll., Lond.; Herbert B. Scott and J. E. L. Alexander Turnly, B.A.Camb., St. Barts. Hosp.; Kenji Takaki, St. Thomas's Hosp.; Francis Thompson, Alfred G. Tresidder, James Turtle, Albert J. Walton, Thomas J. Williams, John H. Wolfe and Percy C. Wollatt, London Hosp.; Alfred E. Weaver, Birmingham Univ.; Salomon J. Weinberg, Owens Coll., Manchester; Arthur D. White and Frank E. Whitehead, St. Barts. Hosp.; Edward K. Williams, B.A.Camb., St. Andrew's Univ.; James A. Williams, Univ. Coll., Lond. Mr. Alexander V. Benson, London Hosp., passed in physiology only.

**Society of Apothecaries of London.**

THE following candidates have passed in:—

Surgery.—J. C. Baggs, Section II.; P. C. Burgess, Section II.; D. Fletcher, F. I. M. Jupe, G. J. W. Keigwin, Sections I. and II.; E. R. Risien, Section II.; W. B. Skelton, M. J. Williams.

Medicine.—J. W. W. Adamson, Section I.; J. H. Beasley, Sections I. and II.; R. C. Bennett; C. E. H. Leggatt, Sections I. and II.; E. T. Longhurst; D. J. Morgan, Sections I. and II.; E. Osborne, Sections I. and II.; J. E. Skey, Section II.; A. W. D. Thomson; P. P. Tobit, Section II.

Forensic Medicine.—J. W. W. Adamson, R. C. Bennett, H. A. Chaplin, C. E. H. Leggatt, E. T. Longhurst, D. J. Morgan, E. Osborne, A. W. D. Thomson, P. P. Tobit, S. C. Wilkinson.

Midwifery.—R. C. Bennett, T. S. Davies, J. W. H. Morrison, E. S. Perkins, R. Rees, S. C. Wilkinson, F. W. B. Young.

The L.S.A. Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: J. C. Baggs, E. T. Longhurst, D. J. Morgan, J. W. H. Morrison, E. S. Perkins, E. R. Risien, W. B. Skelton, A. W. D. Thomson, and M. J. Williams.

**Indian Medical Service.**

THE following is an official list of the candidates for His Majesty's Indian Medical Service who were successful at the Competitive Examination held in London on February 9th, 1901, and following days, arranged in the order of merit as issued from the India Office, August 20th:—

	Marks.		Marks.
Lister, A. E. J.	... 3,246	Bradley, R. J.	... 2,633
Williams, T. F. B.	... 3,135	Loch, E. A. ...	... 2,593
Abbott, S. H. L.	... 3,077	Carter, R. M.	... 2,550
Greig, A. W....	... 3,015	Hagger, R. L.	... 2,545
Lloyd, R. E. ...	... 3,013	Baker, D. G. E. S.	... 2,500
Woods, J. ...	... 2,965	Harley, T. W.	... 2,472
Steen, H. B. ...	... 2,940	McCoy, J. W.	... 2,306
Munro, D. ...	... 2,929	Willcocks, R. A.	... 2,264
Bisset, E. ...	... 2,910	Paterson, T. G. F.	... 2,220
Clements, J. E.	... 2,890	Rai, D. G. ...	... 2,207
Overbeuk Wright, A.			
W. ...	... 2,665		

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**READING CASES.**—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at the office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

### INCREASE OF HYDROPHOBIA IN PARIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR, — I am greatly surprised that deaths from hydrophobia in Paris have not reached a higher figure, seeing that there is in that city a huge Pasteurian Institute largely dependent for its prosperity upon the sale of anti-rabic serums and upon a constant influx of dog-bitten patients. Common sense will supply the links in the chain of this argument.

I am, Sir, yours truly,  
FRED. E. PIRKIS.

Nutfeld, August 23rd.

DR. S. B. (Bedford).—Appendicitis in infancy is not unknown, although it is extremely rare. A case was recently recorded in an American journal, in an infant of three months' old. About sixteen cases in all have been published, of which nine were operated upon, with seven recoveries.

WESTPHALIA.—The total population of Greater London, including the outer ring of suburbs, is now 6,578,984.

M.B.C.S. (Exeter).—Our correspondent's letter is not explicit enough. Nor can we gather when the occurrence described in the newspaper cutting which is forwarded took place, inasmuch as no date is appended.

M. D.—Undoubtedly the attention of the Royal College of Physicians, London, should be called to any Fellow of the College who could be proved to be a shareholder in one of the many sanatoria now exploited for the open-air treatment of tuberculosis. Whether, however, the College would take action or not remains to be seen.

DR. BERNARD (Birmingham).—Copies of the souvenir volumes which were presented at the festival dinner of the Royal College of Surgeons (England) last year, can now be purchased from the Secretary of the College, at 5s. per volume.

### AN INVALID EXCUSE.

"No," said the doctor, "I haven't voted yet, and I am not going to vote. I am not feeling well to-day. Isn't that a valid excuse?" "Not at all," responded the professor severely. "That's an invalid excuse."—*Chicago Tribune*.

E. A.—We were unable to publish your former contributions because the language was so involved as to render the meaning dubious.

**BACTERIOLOGIST.**—The subject is not one to the discussion of which we feel disposed to open our columns.

**YOUNG MEDICO.**—With capital at hand it would be more expedient to take a house and put up a brass plate, and wait for practice in a likely neighbourhood than to embark upon a partnership under the circumstances named by our correspondent.

**BONDHOLDER.**—The custom is founded upon strict equity.

### THE GEOGRAPHICAL DISTRIBUTION OF CANCER.

Y. M. W.—Much useful information in regard to the distribution of cancer in Great Britain will be found in Mr. Alfred Haviland's "Geographical Distribution of Disease." The proposal to compile "cancer maps" is not a novel one, and might be advantageously carried out, especially as the cost would be trifling having regard to the importance of the question involved.

**OMEGA.**—Several cases of dermatitis from wearing stockings impregnated with arsenic have been recorded.

**ASSISTANT.**—The proposal seems to us to be scarcely consistent with the justice of the case, and we cannot advise our correspondent to accept it.

**ETIQUETTE.**—The necessary bond must be given, otherwise the negotiations must fall through.

**COLONIAL SURGEON.**—Apply to the Dean of the West London Post Graduate College, West London Hospital, Hammersmith, W.

DR. E. S.—We have made inquiry, but have been unable to ascertain the present address of the gentleman, the subject of your letter. He is probably still at the front, or thereabouts.

## Appointments.

BEALE, H. E., M.B.C.S., L.R.C.P.Lond., Assistant Resident Medical Officer to the General Infirmary at Leeds.  
DAVIES, W. N. M.D.B.U.I., Certifying Surgeon under the Factory Acts for the Llantrisant and Llanwit Fardre Rural District.  
EVANS, D. E., M.B., B.S.Lond., Certifying Surgeon under the Factory Acts for the Pontypridd Urban District.  
GRUNER, O., M.B.C.S., L.R.C.P.Lond., has been appointed House Physician to the General Infirmary at Leeds.  
HUNTER, WILLIAM, M.B., C.M.Aberd., Assistant Director of the Pathological Institute, London Hospital.  
POTTS, E. THURLOW, M.B., Ch.B. Edin., Resident Medical Officer for Sick Children, Newcastle-on-Tyne.  
RAW, NATHAN, M.D. Durh., F.R.S.E., D.P.H., Visiting Medical Superintendent to the West Derby Union Infirmary, Liverpool.  
SMITH, C. LAWSON, M.B., Ch.B.Aberd., Senior Resident Medical Officer to the Tottenham Hospital.

## Vacancies.

Birmingham Workhouse Infirmary.—Assistant Resident Medical Officer. Salary £100 per annum, with apartments, rations, coals gas, laundry, and attendance. Immediate applications to the Clerk to the Guardians.  
Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence. Also Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.  
Cheshire County Asylum, Parkside, Macclesfield.—Senior Assistant Medical Officer, unmarried. Salary £175, rising to £200 per annum, with board, apartments, washing, and attendance.  
County Asylum, Lancaster.—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, with apartments, board, washing, and attendance.  
County Borough and Port of Southampton.—Medical Officer of Health, Port Medical Officer, and Medical Superintendent of Infectious Diseases Hospitals. Salary (combined offices), £500 per annum.  
Cumberland Infirmary, Carlisle. Resident Medical Officer. Salary at rate of £80 for first six months, and £100 second six months per annum respectively, with board, lodging, and washing.  
East Riding of Yorkshire.—County Medical Officer of Health. Salary at rate of £400 per annum, rising to £500 per annum, with allowances. (See advt.)  
Glamorgan County Asylum, Bridgend.—Assistant Medical Officer, unmarried. Salary £175, with board, lodging, attendance, and laundry.  
Glasgow University.—Additional Examinership in Medicine and Science. Annual emolument £30. Duties to commence in January, 1902. (See advt.)  
Great Northern Central Hospital, London.—Vacancies for House Physician. Salary £60 per annum; Junior House Physician, Salary £30. Board, residence, and washing provided in each case. Also Junior House Surgeon, Salary £30, with board, residence, and washing; and a non-resident Assistant House Surgeon, with Salary at rate of £30 per annum, and partial board. Full particulars of these vacancies will be found in our advertisement columns.  
Kasr-el-Ainy Hospital and School of Medicine, Cairo, Egypt.—Physician to the Hospital and Professor of Clinical Medicine at the School. Salary £E320 per annum and private practice allowed.  
Metropolitan Asylums Board.—Assistant Medical Officer, unmarried, at the Fever and Small-pox Hospitals. Salary £160 per annum, rising to £200, with board, lodging, and washing.  
Northampton General Infirmary.—House Physician (unmarried). Salary £100 per annum, with apartments, board, attendance, and washing.  
Notts County Asylum.—Temporary Assistant Medical Officer. Four guineas per week, with board, lodging, attendance, and washing.  
Owens College, Manchester.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.  
Scarborough, (Borough of).—Medical Officer of Health. Salary £325 per annum, rising to £375 per annum. Full particulars on application to the Town Clerk.

## Births.

FRANCIS.—On August 20th, at Arnold, Notts, the wife of Harvey Francis, M.D., of a son.

## Marriages.

RICHARDSON—MANSELL.—On August 20th, by the Rev. A. E. Mansell, M.A., brother of the bride, Walter Silverwood Richardson, M.D., M.B.C.S., of Melbury, Boscombe, youngest son of T. Richardson, M.D., M.B.C.S., of Highbury New Park, to Ada Mary, youngest daughter of Thomas Henry Mansell, of Temple Balsall, Warwickshire.

WILD—ZWEIFEL.—On August 22nd, at Zurich (Switzerland), Robert Oscar Wild, M.D., eldest son of Franz Wild, of Freiburg-i/B., to Maria Ida, youngest daughter of Henry Zweifel, of Zurich, formerly of Palace Road, Streatham Hill, London, S.W.

## Deaths.

BAKER.—On August 21st, in London, Thomas Young Baker, Brigade Surgeon, Army Medical Staff, Retired, youngest son of the late Rev. W. Lake Baker, Rector of Hargrave, Northamptonshire.  
CESAR.—On August 21st, at Danecale Lodge, Sheppey, Kent, Gerard, and on the 22nd, Eric, the infant twin sons of Julius Cesar, F.R.C.S.L.

## Clinical Lecture ON HYDROCELE. (a)

By A. MARMADUKE SHEILD, M.B., F.R.C.S.,  
Surgeon to St. George's Hospital; Consulting Surgeon to St. John  
and St. Elizabeth Hospital.

BEFORE discussing the diagnosis of hydrocele, a word must be said about *causation*. This is summed up at once by declaring that in a large number of cases of hydrocele no certain cause can be assigned for the disease. The books say that hydrocele is due to a loss of the balance between the absorption and secretion of fluid in the tunica vaginalis, but the fact remains that in a considerable number of cases of hydrocele the sac of the tunica vaginalis is distended with fluid without any rational cause being assignable. A very suggestive point is as follows: A certain number of cases of hydrocele are associated with definite disorders of the testicle. Thus, in syphilis of the testicle, concomitant hydrocele is familiar. In tubercle of the testicle, malignant disease of the testicle, chronic orchitis and epididymitis due to catheterisation, hydrocele is also found, though far more rarely. Thus a certain number of cases of hydrocele are undoubtedly caused by the spread of inflammation to the tunica vaginalis from the testis, or rather from the epididymis. This suggests that hydrocele is usually inflammatory in origin, which is very important in the matter of treatment, for the method of curing hydroceles dependent upon syphilis or tubercle of the testis, is largely bound up in the treatment of the testicular affection which causes and underlies the hydrocele. In some hydroceles a small pedunculated body is found near the head of the epididymis. This is a fetal relic and is sometimes found in the tunica when no hydrocele is present. It is to be wondered whether the rubbing of this substance against the serous surface might produce excess of secretion. The analogy of serous exudation in the knee, due to the rubbing of a pedunculated body from the edge of the cartilage, seems very close.

The *symptoms* of the ordinary hydrocele of the tunica vaginalis, such as are often met with in the out-patient department of a hospital or in private practice, are really exceedingly simple. First of all the shape of the swelling at once tells that it is a distended tunica vaginalis. The swelling is pear-shaped and the neck of it is narrow, so that the cord can be distinguished above the swelling by the pressure of the thumb and finger, showing that no hernia exists, and that it is definitely isolated from the abdominal cavity. Large hydroceles have often a slight constriction about their centre, "hour-glass contraction," which is also very characteristic. There is no impulse on coughing; the swelling cannot be reduced into the belly; and it is very generally translucent. In the vast majority of cases of ordinary hydrocele the position of the testicle is behind the collection of fluid. As a rule the patient is able to distinguish testicular sensation when this part of the swelling is squeezed. It is advisable never to carry out such an

examination, for patients' statements can rarely be relied upon as to their sensations, and a careful examination by transmitted light will usually show the position of the testis by the opacity produced. In a large hydrocele, moreover, the volume of the fluid is so great that it is generally impossible to feel the testis at all, still less to squeeze it. In a few instances of hydrocele the testicle is in front of the hydrocele. This unusual circumstance may be due to malposition of the testicle, the epididymis being in front instead of behind. It may also be caused by the "anchoring" of the testis to the front of the sac by inflammatory adhesions. Thus this condition is found in old hydroceles, which have been tapped many times, and perhaps fruitlessly injected.

The fluid which is contained in hydroceles is highly albuminous, and is generally of a pale straw colour. In some cases of old hydroceles, which have existed for many years, the fluid becomes more opaque and mixed with cholesterin, the colour of old ale, which may greatly mar the certainty of the "translucency" test. Hydroceles associated with sarcomatous testis may contain bloody fluid. It would be more correct to call them hæmatoceles, except that the serum is often in great excess over the blood mixed with it. The fluid in a hydrocele is as a great rarity chylous, and in a case of chylous hydrocele which came from abroad the presence of filaria in the lymphatics was suspected by experts.

All hydroceles are not translucent. Those which have existed for a great many years, and have, perhaps, been tapped many times, and have become chronically inflamed, are notably not transparent. The sac in such cases, from repeated inflammatory attacks, may attain to a great thickness. Such a swelling will be non-translucent, and the diagnosis may be puzzling enough, unless a clear history, of long duration and frequent tapplings be obtained. "Histories" are very deceptive, and sometimes these cases can only be cleared up by exploratory incision. The only way of certainly diagnosing hydrocele with thick walls is by an exploratory incision. It is impossible to distinguish a hydrocele with thick walls from an old hæmatocele except by cutting into it. A swelling may be a hydrocele at one tapping, a hæmatocele at the next, the trocar having pierced a vein, which slowly oozes into the cavity. In these opaque swellings, too, the position of the testis is very problematical. There are frequently inflammatory adhesions, which displace the organ. Hence the incision is safer than the trocar, for the latter may pierce the testis, and lead to the erroneous conclusion that there is a solid tumour.

Confusion between ordinary vaginal hydrocele and soft sarcoma of the testicle ought, in reality, never to occur. Soft sarcomatous growth of the testicle is, on the whole, rare; hydrocele is very common. Soft sarcomatous growth of the testis is non-translucent; it is heavy when lifted up on the hand. It feels solid in some parts, fluctuating in others. The scrotal veins are much enlarged, and the cord above is thickened. An exploratory incision immediately clears the matter up, because instead of opening into a cavity containing fluid, a vascular brain-like tumour is found. The appearance of the patient must not be taken into

(a) Abstract of a Clinical Lecture delivered at St. George's Hospital, London.

account. Large malignant growths of the testis may be found in persons who have the appearance of perfect health.

Ability to feel the elements of the cord above the swelling is the main differential symptom on which to rely in the diagnosis of common hydrocele from hernia. But the shape of the neck of a hernia is different from that of a hydrocele. In hydrocele the swelling is definitely cut off from the abdomen at the external abdominal ring; in hernia there is a wide neck which passes up into the abdomen, distending the inguinal canal.

The treatment of hydrocele is very variable. In a large number of instances, the patients will be satisfied with the swelling being tapped at certain periods. This is termed the palliative treatment of hydrocele, namely, performing paracentesis when the swelling gets inconvenient from its bulk. This operation should be done with an exceedingly fine and sharp trocar and cannula. The patients will appreciate the use of a fine instrument. The hydrocele trocars sold in the shops are often too large for use by a sensible and humane surgeon. The skin of the scrotum should be carefully cleansed, and the instrument boiled before and after using. The sac should be made very tense by the pressure of the left hand before the trocar is introduced, and a spot should be selected free from veins. Radical cure of hydrocele dependent upon disease of the testicle should not be attempted. Under such circumstances it would be unwise to undertake, for instance, the injection method; the diseased testis would be left, and, perhaps, the mischief in it aggravated by the irritant fluid. Tapping is often employed in hydrocele associated with testicular disease, and indeed is sometimes essential in diagnosis. Not until the fluid be withdrawn can the surgeon properly feel the enlarged testis, and estimate its nature.

Another case where the injection cure should not be attempted is where there is a very thick sac. Iodine injected into a hydrocele with very thick walls only makes matters worse. Again, radical cure by injection should never be attempted where there is communication between the sac and the abdominal cavity. Such hydroceles are found in young infants and boys (congenital hydrocele). Many hydroceles in the very young, however, are quite ordinary, and do not communicate with the belly.

One of the objections to radical cure by injection of iodine is its uncertainty. It has been computed by some authorities that 20 or 25 per cent. of the cases of hydrocele treated by injection are not cured. Another objection to injection, especially with iodine, is that the epididymis is generally inflamed by it, and so for weeks after the injection there is a painful, indolent swelling of the testis and epididymis, set up by the injection. The injection is very painful when the iodine enters the tunica vaginalis. Patients have not infrequently been known to faint. Injection of iodine is a remedy which is practised largely, especially in hot countries like India, where hydroceles are very common and very large.

It is important to draw off all the hydrocele fluid; a very common error is to leave several drachms of hydrocele fluid in the sac, and thus when the tincture of iodine is thrown in it probably gets diluted. Many of the instances of "recurrence" after injection may be explained by some faulty procedure on the part of the operator. One to two drachms of the Edinburgh tincture of iodine, which is rather stronger than the usual preparation, is injected into the cavity of the sac. The next step is to shake the sac well, so that the iodine is diffused all over it. This may be acutely painful, and it is wiser to perform the operation with the patient lying down on a sofa. Some surgeons make a practice of previously throwing into the sac of the tunica vaginalis a 2 per cent. solution of cocaine. Not more than a quarter of a grain should be introduced, but it certainly diminishes the smarting caused by the iodine. The day following the injection the scrotum will be swollen and red, and the epididymis inflamed and tender. The patient will sometimes complain of very great discomfort, so that he has to be kept in bed for a few days, though this is

unusual. As a rule, there is more or less epididymitis, and a chronic indolent swelling results, which only slowly subsides.

An injection which, perhaps, is becoming more popular than iodine is carbolic acid. This is at least as likely to cure as iodine, and it is very much less painful. Having emptied the hydrocele, 40m to a drachm of a mixture of equal parts of liquefied carbolic acid and glycerine are thrown into the sac. The scrotum is shaken after injection, so that the whole sac comes into contact with the remedy, and a cure is generally the result. Carbolic acid does not inflame the epididymis to the extent that iodine does, neither does it cause such severe pain. There are various other fluids recommended for injection into hydroceles. All of them, however, are inferior to iodine and carbolic acid.

The method of treatment which most modern surgeons perhaps advise for hydrocele is the radical cure by operation. It is an excellent proceeding in boys or young men who have to enter the services of the army and navy. If the radical cure by excision of the sac is performed, it necessitates resting in bed or on the sofa for upwards of a fortnight or three weeks. The operation is done in various ways. The first is the simple incision method. The hydrocele is incised, and the interior of the sac is lightly rubbed over with carbolic acid with a strength of one in ten; a drainage tube is then put in, and the incision sewn up. This is a good method for small hydroceles in boys. Then there is the method of excision of the sac. The sac of the hydrocele is exposed, and a considerable portion of the parietal layer of the tunica vaginalis is cut away with sharp-pointed scissors. The remaining portion, which covers the front of the testis, is lightly touched over with one in ten carbolic acid, or with a solution of nitrate of silver, twenty grains to the ounce, a drainage-tube is put in and the parts sewn together. The tube is withdrawn in twenty-four hours, and the part carefully dressed and elevated. A certain amount of inflammatory epididymitis will ensue. Especial care must be taken in replacing the organ in the scrotum that the cord is not twisted. This is easy enough to do, and it may lead to very unpleasant after-consequences. In both these procedures the strictest asepsis must be maintained in the dressing, and elevation of the part must be carried out carefully. It is necessary to guard against secondary hæmorrhage. In a big hydrocele the little vessels are very much stretched by the pressure of the fluid, and are diminished in calibre. As soon as the fluid is let out the vessels become engorged. Sometimes a little artery or vein will bleed very persistently into the loose scrotal tissues in these cases. Every single bleeding-point must be tied before uniting the wound and sending the patient back to bed, using ligatures of the finest catgut. If this is not done there may be troublesome secondary hæmorrhage into the scrotum, which becomes "blown up," and bluish in colour.

Male infants sometimes get hydroceles like their seniors, and the greatest alarm is manifested by the anxious female relatives. The symptoms of hydrocele in a baby are exactly the same as those in the adult. A little pear-shaped swelling is observed, which is readily translucent, light showing through it as a red glare. One of the first things to determine is whether the swelling is a congenital hydrocele, and if the fluid can be reduced into the abdominal cavity. If iodine or carbolic acid be injected into the hydrocele of a little child, the scrotum will inflame and may possibly slough, and the life of the infant may be endangered. This is not a fanciful danger. The mistake has been made in practice. The ordinary hydrocele of infants will not infrequently go away if it is left alone, but this will seldom satisfy the parents; they demand some active treatment. The first measure therefore to adopt is to paint the outside of the scrotum persistently with a slightly irritating lotion, such as chloride of ammonium—a saturated solution of the drug in rectified spirit and water. This remedy really cures very few of these cases, but it is harmless.

The next method is acupuncture. The scrotum is made tense, and a fine sharp needle is passed into the hydrocele in various situations; the fluid exudes in drops, and passes into the cellular tissue. This method is advocated in the text-books, but it is not a certain cure. In the case of a large hydrocele in an infant, especially if it has resisted other treatment, incision is the best method. Let out the fluid and rub the interior of the sac with a solution of nitrate of silver, ten grains to the ounce, or one in ten carbolic acid. This may be done by dipping the end of a probe into the "irritant," and passing it lightly over the surface of the tunica vaginalis. A small piece of gauze is inserted for the first twenty-four hours. If the sac is very large a portion of the parietal layer can be excised just as in the adult. The most careful asepsis must be maintained. This is practically very difficult; soaking in a warm boric bath is useful in these cases. There is another point about hydroceles in infants; it is as follows:—In certain hydroceles in little babies the sac goes a long way up into the inguinal canal, distending it, and simulating hernia. This is due to failure of obliteration of the lower part of the funicular process. This variety is called infantile hydrocele. A mere septum may separate the fluid from the abdominal cavity, and careful examination is needful to ascertain that the rupture is not really of the congenital variety, and that the fluid cannot be pressed slowly into the belly.

Encysted hydroceles of the epididymis are said to have their origin in dilatation of some of the fetal tubules which are found in that neighbourhood. The cysts do not, as a rule, attain to large dimensions—about the size of a hazel nut or a walnut. They are tightly distended with fluid, and are sometimes mistaken for solid swellings; indeed, the sensation to the hand is exactly like a double testicle. Whenever there is what seems to be a double testicle on one side, the case will probably turn out to be an encysted hydrocele. These remarkable swellings contain perfectly clear fluid, which is non-albuminous, and also a large amount of phosphates and carbonates. On the addition of nitric acid, effervescence occurs. But inasmuch as a seminal tubule frequently ruptures into them, they become full of spermatozoa, which may give them a milky appearance and spoil their translucency. Then the fluid, of course, becomes albuminous. The walls of these cysts may also be thickened, and this prevents translucency, and an exploratory incision may be needful to establish a certain diagnosis. They are treated in the same way as other hydroceles, namely, by injection, or radical cure by laying them open. Owing to their close connection with the epididymis, the cutting away of a portion of the sac is far the best method to adopt.

With regard to the treatment of congenital hydrocele, which is found in boys and young children, where the fluid can be reduced into the abdominal cavity it would be risky to inject these swellings, for the fluid might find its way into the peritoneal cavity and set up grave inflammation. It is difficult to advise regarding the treatment of congenital hydrocele. Great difference of opinion exists. Many surgeons recommend a truss, and state that the pressure of the pad obliterates the opening. This is always a dubious and tedious method. It is far better to perform an operation like that for radical cure of hernia, the incision being longer and lower down, tying the neck of the sac high up, and sewing together the pillars of the ring, and at the same time excise the front wall of the sac.

Hydrocele with enlarged testis, so-called hydrosarcocele, is often a puzzling condition. Hydrosarcocele is differentiated at once from hydrocele by the fact that when the swelling is lifted up it is extremely heavy, and on palpation the fingers will displace fluid, and come down with a sudden impact upon the solid mass inside. Hydrosarcocele may be non-translucent, except to a very limited degree in front. In the great majority of cases these sarcoceles are syphilitic, and are often bilateral. And the hydroceles may take very irregular form, being, indeed, mere collections of fluid limited by adhesions and false membrane. Hydrocele associated with tuberculous disease of the testis may be found. The hydrocele effusion is very often acute, and if a

young man has hydrocele which is painful and has formed within a month or six weeks it is almost always sure to be due to some disease of the testicle. Such hydroceles should be tapped and the testicle carefully palpated before giving a complete opinion or prognosis. In certain exceptional cases there may be large collections of fluid surrounding malignant disease of the testicle, and the fluid may be bloody. Incision will clear the diagnosis up. Again, old men who use the catheter often get chronic epididymitis and orchitis, and this condition may be associated with hydrocele.

In the treatment of hydrosarcoceles there is no objection to tapping provided care be taken not to wound the enlarged testis inside, and the patient will be considerably relieved. After drawing off the fluid with a fine trocar, if the case is syphilitic, the part should be strapped with blue ointment, and iodide of potassium given internally. In hydrosarcocele, when the testis is tuberculous, in removing the disease which causes it, the whole condition is cured. In sarcoma of the testis there is a progressively increasing swelling, which has probably dated from six to twelve months before, and it will be non-translucent. The story of a blow or "squeeze" is common enough. In addition, the veins over the scrotum are markedly enlarged, and there are frequently nodules of growth in the cord, and to the hand the swelling is very heavy. As soon as incision is made into it the nature of the growth is determined.

## A STUDY IN HEREDITY: IN ITS RELATION TO IMMUNITY IN TUBERCULOSIS.

By HERBERT MAXON KING, M.D.,

Delegate for the United States Government to the British Congress on Tuberculosis, 1901.

THE material for this study was taken chiefly from private practice, with the addition of a few cases occurring in the author's hospital service, whose opportunities for close observation at the time and personal knowledge of the subsequent histories of the several cases after leaving the wards were sufficient for the purposes desired. Some apology it would seem necessary to offer for presenting before such a body as this honourable congress deductions and conclusions based upon researches in so limited a number of cases as this present study includes, more especially since certain of the conclusions are at variance with traditional axioms in phthisiology. However, in the present inquiry all facts were collected and recorded personally and without prejudice, so that, however unique may be the conclusions to which a study of my cases has led, they are warrantable at least so far as the limit in number of observations will permit. The material at my disposal consists of carefully recorded histories of 242 cases of pulmonary tuberculosis. In every instance I have endeavoured, besides studying the influence of heredity and environment, to ascribe, whenever possible, a cause for such peculiar manifestations of the disease as became apparent, and also to establish the relation which certainly exists between the selective activity of the disease and hereditary influence.

The theory that a phthisical parentage predisposes the offspring to the disease by virtue of heredity, while very firmly grounded in the medical mind, and still more so, of course, in that of the laity, has nevertheless, I believe, always been a subject of more or less controversy, and especially since the isolation of the specific micro-organism. Without, however, entering upon a *résumé* of this controversy, which the limits of the present occasion and inclination alike prescribe, I have, like most phthisio-therapeutists, always been disposed to discredit the theory and, until within the last four or five years, to place a negative value upon "family history"

except in so far as a tuberculous parentage subjected an individual to additional risks of infection. The following instance, which came to my notice several years ago, first suggested to me that there might be a certain degree of *immunity* conferred to the offspring of phthisical parents. I published this instance as an illustration in 1898, in a paper in which I first ventured the opinion that "phthisical parents might impart to their progeny a certain immunity to the disease." (a) As it is brief and to the point I quote it:—"A clergyman and his wife, the latter having borne two children after developing pulmonary tuberculosis, took into their household by adoption the orphan child of a non-tuberculous family. After surviving the birth of her last child six years the wife died. Both of her children are living and in excellent health to-day, the younger having passed her twentieth year. The adopted child came under my observation at the age of seventeen years, having developed acute pulmonary tuberculosis from which she died."

To adopt as a working theory this idea of conferred immunity in tuberculosis against all traditions requires, I admit, considerable temerity. One is constantly confronted with the question of inherited predisposition and cannot fail to be influenced by the demonstrable fact of "percentage heredity," a term employed by Dr. J. Edward Squire, to express in percentage the difference between the number of the offspring of consumptive parents subsequently developing tuberculosis and that of the offspring of non-consumptive parents subsequently developing the disease. Dr. Squire's paper was published in November, 1897 (b), and was a most valuable contribution to the subject of hereditary influence in phthisis. In it he refers to a former paper, by himself, read before the Royal Medical and Chirurgical Society of London in December, 1894, on "The Influence of Heredity in Phthisis." Both papers were based upon results of thorough investigations in sufficient numbers of instances to warrant the adoption of his conclusions as *standards* in future inquiry along this line. I have no hesitation in accepting them as final so far as they are carried.

This "percentage heredity" Dr. Squire found to be only 9.51, and he points out that it is easy to explain this small percentage of influence due to parents by the additional risks of infection to which the children of phthisical parents are exposed. Now, it has seemed to me almost certain, that if these children of consumptive parents, especially that usually weak and under-nourished class from which Dr. Squire made his observations, were not in some manner protected, this percentage would be much larger, since in such cases we may take it for granted that all of them fulfil every required condition for the development of the disease. Therefore, while admitting the fact of a "percentage heredity," the very figures which express it are such as to support the theory of an hereditarily conferred immunity.

It is, I think, the rule to find among the children of consumptive parents poor nutrition, imperfect digestion, and other functional derangements, together with certain almost characteristic marks of degeneracy in the bony skeleton, the long, shallow, and comparatively immobile chest, prominent scapulae and sunken sternum. Yet with such features, more or less marked in a family of several children of consumptive parentage, it is a matter of common experience to see them all reach maturity without succumbing to an affection which, from the very nature of things, it would seem inevitable that they could not escape; while, on the other hand, the

more acute, unresisting, and progressively fatal cases, I think, it is the common experience to find among those of a much more normal physical habit and where the source of infection is frequently most difficult to locate. Observations of this character, however, prove nothing, of course. It is from the analysis of a given number of cases occurring under somewhat similar conditions, and among individuals of like hygienic and social relations, that statistics, to be of any value, must be drawn. Even so obtained statistical figures are very apt to be misleading, and are no doubt open to much just criticism on that score. I would not attempt to prove a theory by conclusions based upon an experience in 242 cases unless the results were very positive, but I would very much like to provoke discussion of a subject which cannot be devoid of interest in such a society as this Congress represents, and to stimulate further inquiry into a matter of such far-reaching importance. If I shall have accomplished this object I shall rest content with the assurance that the theory will take care of itself.

To proceed, then; the cases which I have utilised in this series have occurred in a community for the most part moderately well-to-do. Small tradesmen, mechanics, artisans, operatives in wholesome, well-lighted, clean and well-ventilated furniture factories, and small farmers. Nationality has been various. Next to American born, Dutch, German, Scandinavian and Irish predominated. Because of the comparatively recent development of the section of the country in which my observations have been made, and the more or less migratory habits of the first generation or so of foreigners in America, it has been the exception rather than the rule to be able to secure accurate data beyond the immediate parentage; but while it would be desirable to secure such data for purposes of demonstrating the transitory character of inherited immunity in tuberculosis, if such exists, for present requirements it is, I think, needless to do so.

The individuals comprising my series, by reason of their comparatively well-to-do condition and the customs prevailing in the locality, have none of them experienced the vicissitudes incident to life in the cheap tenement house districts of large cities. As a rule this class lives in small, compact but well-lighted and comparatively new frame houses, separated from each other by lawn spaces, and heated by stoves, or occasionally hot-air furnaces. In the course of inquiry, when phthisis was found in either or both parents, it was the rule, with very few exceptions, to find it to have been present during the early life of the case under observation, and to have been the cause of death. Frequently it could be traced back prior to the birth of my patient, and to have persisted with remissions in activity for a considerable time afterward; more particularly was this the case among women, where in several instances I have satisfied myself of its presence during most of the child-bearing period. Without exception these instances occurred among women of consumptive parentage. Of course, positive demonstration of the long existence of the disease in these cases was obviously impossible beyond the time of my own acquaintance with the case, and as scientific evidence, therefore, such citations are valueless.

Of my 242 cases, the parents, one or both, had phthisis in sixty instances, or 24.8 per cent., while the parents were non-phthisical in 182 instances, or 75.2 per cent. Of the sixty who had phthisical parents, the father was found to have been affected in thirty-one cases, or 1.28 per cent., the mother in twenty-nine cases, or 12 per cent., and both parents to have been phthisical in four instances, or 1.6 per cent.

(a) *New York Medical News*, December 3rd, 1898.

(b) "Heredity in Phthisis," *American Journal of Medical Sciences*, November, 1897.

It was more common in my experience to find a previous tuberculosis in a brother or sister or both than in the parents, and in such cases an almost perfect history of infection could be traced. It was often possible to designate the date of infection to within a few weeks, and in some instances to within even narrower limits, a point of some value in estimating the period of incubation, or studying that questionable quantity, the "period of latency."

Seventy-four of my cases, or 30.6 per cent., gave a history of previous tuberculosis in a brother, sister, or both, and it is a point of some interest that of these seventy-four only twenty-two were of phthisical parentage; furthermore, as will be recalled, there were sixty cases in which one or both parents were phthisical, and of these twenty-eight had brothers or sisters who were non-phthisical; or, to put it a little differently, out of sixty families with phthisis in one or both parents, there were twenty-eight instances of the disease affecting only one of several children. This does not, of course, imply that in the remaining thirty-two there was necessarily more than one child affected, for in many instances the patient was an only child.

It will further be seen that while twenty-two individuals having a phthisical parentage gave a history of previous tuberculosis in one or more brothers or sisters, there were fifty-two cases of non-phthisical parentage giving such a history.

These figures would certainly fail to show an hereditarily conferred predisposition to the disease, and if they have any value at all, it is on the side of a conferred immunity instead. Of the whole number, —242 cases—I can, at present, account for 235; of these 132 are living, and 103 have terminated fatally. Although it has a negative bearing upon the present inquiry, it may be of interest to note that in each group the percentage of phthisical parentage is the same. That is, of the 132 living, 26 per cent. had phthisical parents; and of the 103 dead, there was also 26 per cent. whose parents, one or both, had died of the disease.

The most interesting development in the course of this investigation has resulted from a study of the 103 fatal cases. As above suggested, 26 per cent., or twenty-seven cases, were found to be of phthisical parentage, while seventy-six had non-phthisical parents. My histories show that the average duration of the disease from its apparent incipency to the fatal termination was, in the incidence of the twenty-seven cases of tuberculous parentage, 4.01 years, while in that of the seventy-six cases of non-tuberculous parentage it was 2.93 years, a difference of more than a year in favour of those having a phthisical parentage.

Now it has been my experience that the development of phthisis in individuals living or having lived for any length of time with consumptive parents is more subtle and indeterminate as to commencement than is the case in the more robust offspring of non-consumptive families, where the onset of the disease is far more apt to be comparatively sudden, and consequently more easily determinable as to date of commencement. In this latter class the so-called "pre-tuberculous stage" has no existence as a rule, and the measurement of the duration of the disease is accordingly much simplified. This "pre-tuberculous stage" is, in reality, I am sure all will admit, a part of the life history of the disease and should be included with all subsequent stages of phthisis when estimating the duration of the disease in a given case; but because I desired to free my inquiry as far as possible from misleading results or error in judgment as to what was and what was not the early stage of tuberculosis, I have, in this series of observations, limited the definition of phthisis to a stage of the disease where it has been clearly demonstrable.

I have, therefore, a considerable leeway over and above the one year in favour of my cases with consumptive heredity, and had I included the "pre-tuberculous" stage in my estimates I am very certain that the difference in duration of the disease between the two classes would have been more marked than it is. I have, like many other observers, frequently demonstrated the presence of tubercle bacilli in the secretions of the air passages of healthy children and adults occupying apartments with consumptives, particularly consumptive parents, when subsequent events failed to show a development of tuberculosis from their presence. As an illustration: in a family consisting of a widow and four adult children, one of whom, a daughter, has been a consumptive for seven years (easily demonstrable during the whole of that time), the father had died after having had phthisis for upwards of twenty years. The consumptive daughter above referred to continued the local focus of infection after the death of the father, although to a less dangerous degree because of sanitary education. A few years ago one of the sons contracted typhoid fever, during the course of which the usual bronchitis developed. In the expectorated matter many tubercle bacilli were found during the course of the complication. Doubting the diagnosis of typhoid, I verified it by a positive Widal test and the diazo reaction in the urine. There was no pulmonary consolidation, and the case ran a typical course with good recovery and, to my surprise, has never shown the least evidence of tuberculosis since, although during several subsequent winter attacks of bronchial catarrh a search has been made for bacilli. I might add that in this family every one of the four children is apparently a classical subject for phthisis, with the long, shallow, and immobile chest, and the imperfect nutrition above remarked; yet, though having lived almost their entire lives in the house with a consumptive, only one has developed the disease, and that one presenting every evidence of being able to successfully resist a fatal termination for many years to come.

Vital statistics show a gradual declining death-rate from phthisis. This is doubtless in part the result of improved methods in restricting the spread of the disease, but, in view of many facts, is no doubt also due in part to one or both of two not unimportant factors—*i.e.*, natural selection and inherited immunity. If the conclusions reached by Otto Naegeli, based upon 500 autopsies made in the Pathological Institute of Zurich, on bodies of individuals dying of various diseases, shall be verified in other parts of the world, the question of inherited immunity must be acknowledged to play a very essential part in the decline in frequency and severity of phthisis. Naegeli found indubitable evidence of active or latent tuberculous lesions in 97 per cent. of all sections in individuals between eighteen and thirty years of age, and in 99 per cent. of those over thirty years of age. (a)

If it is true that all individuals reaching thirty years of age develop tuberculous lesions which are demonstrable post-mortem, the only explanation for the comparatively small percentage who die from phthisis lies in that of an inherited or acquired immunity.

Within the memory of men still living there was no phthisis among the Indian tribes roaming the high plateaux of Colorado, Arizona, and New Mexico. But a very few years after it became popular to send white consumptives to those regions as a therapeutic measure; the infection thus spread among the Indians gave rise to an almost epidemic form of phthisis of an unusually acute and fatal type. The same is true of the negroes of certain sections of the

(a) Virchow's Archives, May, 1900.

Southern States, whose heredity was entirely clean so far as tuberculosis is concerned, yet who succumbed in prodigious numbers as soon as the infection was brought them by the consumptive whites from the north, who, by reason of their greater immunity, often recovered by virtue of a climatic influence which, like that of Mentone, was insufficient to protect the unimmunised native.

The older writers, in speaking of the influence of family history in phthisis, often remarked upon the frequency with which the disease affecting the grandparents would skip one generation to reappear in the grandchildren. If there is truth in such a statement, it would seem plausible to attribute the phenomenon to an inherited immunity sufficient to protect the children, but not sufficiently permanent to protect the second generation. In my own experience I have not attempted records with this idea in view, and therefore have no facts to bear it out.

I must acknowledge one rather serious omission in the course of my investigations in the present series of cases. It was to a certain extent unavoidable, but in future inquiry along this line it seems to me most important that it be not again omitted if we are to arrive at any positive conclusions by such methods as I have employed. It lies in my failure to determine whether or not, when there was a consumptive parentage, the parent affected was tuberculous prior to the birth of the patient under consideration; for if such were not the case, and the patient became tuberculous only after the child was born, obviously any immunity to the disease which the child afterwards developed would be simply an acquired one; and if the child afterwards became phthisical, the disease in the parent would have no more bearing upon the case than had it occurred in a brother or sister. In such a case it would be quite proper to include it in the class of non-phthisical parentage, for the purposes of present study.

Briefly then, to summarise the results of observations in my series of cases, it will be remarked that:—

(a) Of 242 consecutive cases of phthisis, one in every four gave a history of phthisis in the parents.

(b) Nearly one in three gave a history of previous phthisis in a brother, sister, or both.

(c) More than two-thirds of those giving a history of previous phthisis in brother, sister, or both, had non-phthisical parents.

(d) As a rule, in the incidence of individuals of phthisical parentage afterwards developing phthisis, a much longer period was found to exist between the supposed exposure to infection and the subsequent appearance of the disease, than was the case in the incidence of those giving a non-phthisical heredity.

(e) Of 103 fatal cases of phthisis, the average length of life after development of the disease of those giving a history of phthisis in the parents, was to that of individuals of non-phthisical parentage approximately as 4 : 3.

So that, from a study of the foregoing series of cases, the following conclusions naturally follow:—

First, the percentage of consumptives having a tuberculous parentage is actually smaller than that having a non-tuberculous parentage, and much smaller than would be more than accounted for by the additional risk of infection to which the former class is subjected; and

Second, tuberculosis in the parents renders to no inconsiderable extent an immunity to the disease in the offspring, an immunity which, of course, is but relative, and not sufficiently protective, but still demonstrable, as is shown by increased resistance to the progress of the disease and increased tendency to recover among this class.

## EPILEPSY AND ITS PHENOMENA.

By GEORGE M. FOY, M.D., F.R.C.S.,

Surgeon to the Whitworth Hospital.

THE group of symptoms that the early Greek physicians named epilepsy remain after a long past centuries unexplained. And the disease remains an opprobrium to medicine and a mine of wealth to quacks.

From the great progress made in the study of cerebral pathology it might naturally be expected that more light would be thrown on this obscure disease, but so far we know little more than what we did when Moore's edition of Van Der Kolk's monograph was published in 1859. The study of the aetiology of the disease in Great Britain seems to have been neglected since Dr. Duckworth published his work on the efficacy of bromide of potassium in epilepsy and certain psychical affections in 1865.

Recently, on the Continent, there appears to be a revival of interest in the disease and its phenomena. To place a summary of some of the more interesting accounts that have been published is the object of this paper. M. Bourneville, at the recent meeting of alienists and neurologists of France, told of five cases of epilepsy which came under his notice in which the attack was followed by a rash which resembled purpura in some parts and in other parts took the form of rows of flea bites.

The face and neck were attacked in all of them, and in one case the eruption spread all over the body.

Except for the epilepsy, all the patients enjoyed good health and were not at all anæmic. He drew attention to the similarity of these rashes, which remained but a few hours, to the stigmata, which are permanent, of the hysterical.

M. Crocq told of a patient sixty-five years old, who, after each epileptic attack, suffered from a purpuric rash on the face and from hæmaturia. He placed the patient on moderate doses of tincture of the perchloride of iron—the hæmaturia ceased, and never afterwards had he the purpuric rash. M. Doutrebente drew attention to the association of epilepsy and hæmophilia—a patient of his died from bleeding due to the extraction of a tooth. M. Bourneville mentioned that none of his five cases suffered from hæmophilia.

In this connection the experiments of MM. Dide and Sacquepin are interesting. They drew off some of the cerebro-spinal fluid of epileptics immediately after an attack and injected it into guinea-pigs. The first effect of the injection was to cause the animals to fall forward, to become stupefied, and to have convulsive movements. After the attacks the cerebro-spinal fluid when injected in doses of from four to one hundred cubic centimetres produced violent general convulsions. A dose of half a cubic centimetre injected produced death, the fatal result occurring from a few minutes to half-an-hour after the injection. In every case death was preceded by epileptiform and tetanoid convulsions.

## PRÆPHTHISIS AND PHTHISIS IN RELATION TO CONSTITUTION.

By WILLIAM H. PEARSE, M.D.Ed.,

Senior Physician, Plymouth Public Dispensary.

IN February last I was favoured with space in THE MEDICAL PRESS AND CIRCULAR for a paper on the "Correlations of Phthisis." Since then I have gone through my case-book for the last two-and-a-half years, and have cast into the following Table an abstract of all the cases of præphthisis and phthisis which have presented.

In my February paper I viewed the varied deviations of function and structure of præphthisis and phthisis

in their relation to heredity, and to the epi-meso- and hypo-blast. I also indicated the principle of Atavism, both in relation to function and structure; but, further, I especially pointed to the great principle of Alternation, i.e., that deviations of function in one generation had biological and essential continuity with deviations of structure in other generations and *vice versa*, and, yet more, that such fundamental deviations or conditions, in other individuals and generations, were expressed or shown by weak molecular bonds of the bioplasm of one—usually one—or both lung apices, and that thus the lung apex partially dying too early in the life of the individual, gave a nidus for the stronger molecular attractions of the unicelled bacillus. The greater basis of phthisis was thus seen to be in the constitution. My cases carried the mind far more toward the great laws of the biological evolution than toward bacilli as measuring the fuller Form of phthisis. (a)

Having in February last pretty fully enlarged on such facts and hypotheses, I shall not go over the same ground now, but simply record in the Table the results of two-and-a-half years' observation; following the Table I shall add a few illustrative cases, and the "illuminating Ideas" (Coleridge) which flow from them.

The Table shows in the two groups of præphthisis and phthisis a great similarity in the deviations, both of function and structure; a Continuity is seen in the two groups; prior to the final bacillary development in the cases of phthisis, the two groups are indistinguishable; in other words, phthisis has a long pre-stage of deflected function and structure; we may not be able to state this orderly continuity and pre-stage with the precision of a syllogism or a sum, but it is not the less clear if we have any approach to a justly wide Method of viewing the biological evolution. The Table also shows that the continuity of præphthisis and phthisis has its roots far back into heredity.

*Function.*—The most striking condition of the early stage of phthisis and præphthisis is the sensation of weakness. A great number of patients, both præphthisical and in phthisis, have told me that the first thing they found wrong was an extreme sensation of weakness; in many such præphthisical cases there was no wasting, but the feeling was present in fine young men and women, and existent often for a year or two prior to any other sign or symptom of disease. It is but to deceive ourselves with "words," (b) to rest for explanation of this phenomenon in such expressions as "exhaustion of the nervous system," or in "muscular weakness"; the conditions of such "weakness" are general, in defective molecular modes, and deficient potential vital "energy" of bioplasm, conditions too subtle for any of our present powers of analysis.

The same class of cases will often say that for years they have suffered from sensation of "coldness," especially from cold feet at night. The explanation must be sought in the same general deficient "potential" which is the basis of the "weakness." "Heats" and sweating were complained of far less often than was "coldness."

Præphthisis correlates with much disturbance of the sexual system, of which amenorrhœa is the most frequent phenomenon, sometimes, but rarely, total amenorrhœa; on the other hand, menorrhagia sometimes exists. But both these conditions so often exist where there is no tendency to phthisis, that they must not be looked on as "causes" of phthisis. At the same time, observation of Nature shows that in those who will eventually pass into phthisis, there is a deficient or disturbed correlation of the great fundamental sexual origins; even barrenness has been seen to have correlation with, and to be atavic to, those conditions of bioplasm which have passed into phthisis.

(a) The word *Form* is preferable to the word *Law*; Bacon, following Plato, makes the word *Form* to imply all the contained processes of Matter and Energy, going along with the inspiring Ideas which should arise from a view of facts, "That forms were the true objects of knowledge." Coleridge beautifully expounds the same philosophy in his treatise on "Method."

(b) Bacon says, "... yet certain it is, that words, as a Tartar bow, do shoot back upon the understanding of the wisest, and mightily entangle and pervert the judgment."

When a refined, spiritually-minded, poetic girl of from sixteen to eighteen, and who has a fine type of physical formation, is brought for amenorrhœa, it is a miserable conception of biology and pathology to confine our mental view to the sexual organs. The sexual organs are but differentiations of a universal energy of bioplasm. We have to deal, in such a case, with modes or defects of bioplasm of infinite delicacy, defects which are in continuity with that failure in energy in the attraction of the molecular bonds of lung-apex bioplasm which in a few years may give nidus for the molecular attractions of the unicelled bacillus. The amenorrhœa of the young girl of the type I have depicted, and her future phthisis, are parts of a progress of universal laws acting in orderly continuity.

Contrast the above-typed girl with the rapidly developed, plump, fair, and somewhat lethargic, young country girl of the S.W. counties, who has amenorrhœa and is a little chlorotic, but who will balance the just order of evolution in a year or two, and live to bear and suckle from fifteen to twenty children, and we shall see at once how deep down in the constitution are the paths to phthisis in the former and how absent they are in the latter; the complexity—yet so orderly—of the involvements are not yet unravelled, but we must justly learn by observation and analogy long before we have mastered the subtle bio-chemistry and bio physics of the different types. It is sufficient here for me to point to the "constitution" of a type of young woman who, now in amenorrhœa, will, in absolute continuity, pass in future years into phthisis.

Trousseau long ago pointed out the sometimes danger of giving Iron, and of forcing the monthly function, in those who tended to phthisis. In the delicate-typed class of girls to whom I have referred, the absence of the monthly function seems to be a normal or natural and harmonic condition, justly correlating with the whole system, and it may be most dangerous to hastily disturb the balance of the complex system. In modern theory, we may thus aid to create a nidus for the bacillus in the lung apex. The monthly period should be re-established by the slow and harmonic development of the whole system. I make these remarks because chemists tell me that they sell Bland's pills for the gross to young girls—and old—under the hope or fancy that the complexion is improved by their use.

The basis of the future phthisis may often be seen years prior to the bacillary stage in a prevailing poorness of appetite, and especially in a repulsion to fat, excepting butter, which holds an organic acid in its constitution. Young people who will repel every particle of fat meat, will eat buturic-acid-butter with avidity; often, too, such patients will readily eat the fat of smoked or salted meat. I have known many who, repelling all other fat of meats, would heartily eat the fat of roast pork. Such facts point to some "deep, hidden law" in the bio-chemistry of the cell and system.

In a very great series of cases I have known the præphthisical and phthisical possessed of a passion for onions, raw or cooked; hundreds of young, delicate præphthisical patients have told me of their passion for onions, and that no food agreed with them so well, or seemed to give them so much strength. Is such result due to the energy of the allyl molecule? Such facts put us on the path leading to foundations in pathology.

Similarly, though in a less degree, there is often in the præphthisical a great desire for pickles. I always encourage such longings, as promoters of appetite, purifiers of the *primæ viæ*, and, it may be, just balancers of metabolic processes. The Native of India has a passion for limejuice, tamarind and other fruits; by them his anæmia, night blindness, proneness to vast ulceration of the intestinal mucous membrane and skin are prevented and relieved.

Both with the Native of India and the præphthisical European, the benefits from such kinds of food are not to be explained by any present chemistry; such longings are the absolute expressions of orderly laws, as much so as when the stone falls, or the needle points to

the N. The full Form or nature of phtthisis is involved in these allyl and other longings.

*Structural.*—But the profound nature or Form of phtthisis is not only seen in the long preceding deviation of varied functions, but also in marked deviations of structure. As I have on former occasions pretty fully depicted the structural changes of the præphtthisical and phtthisical (a), I shall now confine myself to a mere reference to the facts of the Table, nor shall I repeat an attempt to correlate such structural deviations to the blastoderm and its layers.

Following the order of the Table, in the præphtthisical there is often marked deviation in the hands; the hands are often unduly large, long, and cold; now and then the hands may be unduly small; the clavicles are often unduly big; they too, now and then are small and fine. I have seen young men, otherwise fully grown, in whom the entire thorax had almost ceased to develop during many years. In other cases, children of sixteen had hardly grown since ten or twelve years of age.

But more frequent than any of the above deviations are those of the terminal cartilages of the nose. Unduly large terminal cartilages which are non-symmetrical on the two sides and non-mesial, and which tend to point laterally, semi-truncated *a/s nari*, have a very marked correlation to phtthisis. These structural variations are often atavic and alternate with phtthisis.

L. B., f., æt. 17, came for "weakness." No physical signs in chest. Nose to left; terminal cartilages big and unsymmetrical; nails rounded; eyebrows big. Father and brother died of phtthisis.

S. F., f., æt. 35, came for "weakness." No physical signs. Nails almond-shaped; index nails most so. Terminal cartilages of nose very pointed laterally. Her father, mother, and brother died of phtthisis; also her mother's sister and brother.

J. S., f., æt. 27, came for "weakness" and cough; suffered extreme sensation of coldness; no appetite; she had phtthisis of right apex; nose sharp at end and pinched; slight median terminal sulcus; one brother died of phtthisis.

*Skin system.*—I am carried far away from some recent utterances: "Phtthisis . . . is the work of a microbe, the tubercle bacillus discovered by Koch," by the great stream of præphtthisical and phtthisical cases, of which the foregoing remarks and cases are but a tiny part; nor less enlarging to our view of phtthisis, is the study of its correlated skin deviations. Nails cupped, transversely ridged, exquisitely fine, friable, &c., each may correlate with phtthisis, sometimes in the same individual, but more often as alternate and atavic phenomena. Heavy eyebrows which tend to meet in the centre, coarse and abundant hair, ears which stand out at a big angle, conditions of teeth, such as translucent enamel, small upper lateral incisors, congenital absence of the upper lateral incisors, all these correlate with phtthisis.

I would illustrate these præconditions, these wide correlated formative stages of the soil, in which the bacillus can flourish, by a great array of recorded cases, but I hope that I have said enough to make clear the correlatability and continuity of Function and Structure, and yet further, their atavism and alternation, extending sometimes over many generations.

*Heredity.*—Though at the same time a constitutional base was admitted, the world has lately been authoritatively told that "phtthisis is not an inherited vice in the constitution. . ." This dictum recalls Bacon's words, "It is almost necessary in all controversies and disputations to imitate the wisdom of the mathematicians in setting down in the very beginning the definition of our words and terms." In this instance we should have to define the word "phtthisis."

If we assert that phtthisis "is the work of a microbe, the tubercle bacillus discovered by Koch," and confine our view to that final stage only; or if we are enchained by nosological definitions, that "phtthisis is a disease of the lungs," we may fairly assert that "phtthisis is not an inherited vice." But the great stream of præphtthisical and phtthisical cases which passes before me has shown that the final lung bacillary invasion is but a very minor

part of the full Form of phtthisis; if we would rise to a just conception of phtthisis we must use the Method of Evolution and Continuity, in general, as applied to the organic kingdom; our definition of phtthisis then would embrace the modes of the ovum and sperm cells, the blastoderm and its layers; and yet more, phtthisis involves the differentiations of those layers as eventually passing both to function and structure. Why should the physician and pathologist be limited and confined to a verbal, nosological, or bacillary foundation or measure of disease, whilst the trend of all other organic and biological science is toward common forms, general alliances, and unity of law and order. Phtthisis thus should be viewed from its primary roots and origins up through all its transitional stages; and in this Method it will be found that Heredity holds an ever present influence.

*Slow Evolution.*—With inherited tendency, the potential energy of the lung apices lasts on variously to adult age; then expiring, the bacillary bioplasmic attractions overpower those of the lung. It is a common experience that even then some patients will last for many years, so nearly perfect are the vital bonds and energy of lung bioplasm; in other cases the lung is destroyed in a few months.

Parallel phenomena are seen in a family where several die of phtthisis, and one escapes; no other explanation seems possible, but that that individual who escapes has received at birth a higher potential in the lung apex bioplasm. I think that we should carry into our view of disease the largest general views of biology, in its wide correlations and great periods of time, which we, in this day, ever apply to paleontology, geology, physics, and to all other orderly and naturally evolving phenomena of Nature. To cite one illustrative case. S. E., f., æt. 38, has come to me every year for twelve years past, sometimes for "weakness," at other times for varied neuralgic pains, at others for "indigestion"; she is not wasted. I have never found any physical signs in the lungs. The nose has big terminal cartilages, the nails are rather rounded, the right index nail cupped, the right middle nail has transverse ridges. She had a child twelve years ago, but has since been barren. Her father and two of her brothers died of phtthisis. From a wide biological view, I am compelled to view this woman's deviations of structure, and especially her deviations of function, as in absolute and orderly continuity with the phtthisis of her father and brothers; she has been all these years in hovering unstable biochemical equilibrium. But how exquisitely delicate in difference must be the modes and bonds of her lung bioplasm, which save her from those losses of energy, which led to a fatal result in her father and brothers. I am compelled to fall somewhat into the Method of the naturalist who is studying variation in species—present or paleontological—when I am in presence of such instances of "variation" and continuity in disease.

*Bacilli.*—The experienced eye can, in a large proportion of cases, predicate of certain individuals, that at early ages they will pass into phtthisis; with no less certainty can we say that individuals of another type will never pass into phtthisis.

The types of the præphtthisical and phtthisical are approximately given in the Table.

One may justly hold the hypothesis that the bioplasm of an organic cell can be resolved into the substituted ammonia groups of alkaloids, &c., down to more stable elementary bodies—carbon dioxide, urea, ammonia, water, &c., by and through the inherent bio-chemical dynamics of its contents; but it is no less true that parallel changes are often set agoing by the molecular motions of unicelled organisms, yeasts, bacilli, &c.

Thus theory and experience both accord with the great place which bacilli hold in the last stages of the lung destruction of phtthisis.

But the pollen falls in vain on the stigma, except at certain recurrent harmonic modes or molecular motions of the stigma's protoplasm, and so throughout the vegetable and animal kingdoms, the molecular activities of the sperm cells are in vain, except in presence of certain harmonic modes and motions of receptivity and absorption.

PHTHISIS AND PRÆPHTHISIS AND THEIR CORRELATIONS.

27	8	7	10	2	21	20	2	23	2	6	2	10	10	5	4	4	1	3	2	3	2	13	2	2	4	3	5	13	2	1	1	1	1	1	1			
21	13	14	5	2	16	13	3	15	3	5	2	6	5	2	4	1	1	3	3	1	2	13	2	3	4	2	3	8	2	1	1	1	1	1	1	1		
23	8	7	10	2	21	20	2	23	2	6	2	10	10	5	4	4	1	3	2	3	2	13	2	3	4	3	5	13	2	1	1	1	1	1	1	1	1	
23	8	7	10	2	21	20	2	23	2	6	2	10	10	5	4	4	1	3	2	3	2	13	2	3	4	3	5	13	2	1	1	1	1	1	1	1	1	1

The facts of germination by fission do not militate against such theory, because the creative power of sperm and ova cells are but differentiations of a universal energy and motion existent, more or less, in every cell of the organism.

Darwin says:—"All the forms of reproduction graduate into each other, and agree in their product, for it is impossible to distinguish between organisms produced by buds from self-division or from fertilised germs."

Similarly, the tubercle bacillus falls in vain on the lung bioplasm of certain types of men and women; hypothetically, we may assert that the lung molecular bonds are stronger than are those of the uncalled tubercle bacillus.

The Table shows the congeries and correlations of functions and structure, extending often back through many generations, of those in whom the molecular bonds of the bioplasm of the lung apices cease their powers too early in the life of the general organism of the individual.

This constitutional mode or state, correlating with the most fundamental laws of the biological evolution, seems to loom up as the major Form of phthisis.

In view of the various phenomena of function and structure, and of their wondrous commingling and correlations the words of Goethe arise—

"Thus the whole of the throng points to deep-hidden law,  
Points at a sacred riddle."

*Treatment.*—Treatment should in the main be prevention; recognising that a child is not of robust type we apply the tonic regimen—exercise, pure outer air, in all its known and unknown mighty potentialities of sunshine, light, motion, chemical action, electric energy, &c. The atmosphere is truly cosmic in its correlations to life and health; by exercise in the open air we use the greatest fulness of all the energies which make for and are true parts of life. Pure air in the day and the active metabolism which exercise produces; pure air at night, but with judicious warmth. Such physical energies should be used in no excess, but in harmony with the capacity of the system to enjoy them, for different individuals need them in different degrees. Moderate, but continuous through years, should be the method of the tonic regimen, in harmony with the processes of the growth and evolution of the organism. We find that those who are hovering on the brink of phthisis get a great restoration by a month or two of wandering in the summer on Dartmoor. The body, mind, and feelings are all greatly influenced for good; I conceive that the restoration of a bright and happy mental state is of supreme importance in warding off phthisis. My impression is, that it is better to send an early phthisical case to wander on the moors, and to be there mentally interested in its geology, botany, archæology, and scenery, and to be absorbing its full stimulating physical and psychical influences, than to send such a case to a "home." I should say to the patient—"Go and enjoy yourself, 'eat drink, and be merry,' and don't take a clinical thermometer with you!" When I recall remembrance of the great stream of phthisis and præphthisis which I have seen during the past twenty-five years I am compelled to accept the words which Dr. Baly used after his grand review of the conditions and phenomena of cholera, as no less true in reference to phthisis:—"Moreover, no *simple* theory (the italics are Baly's) that has yet been proposed, will account for all the facts in the history of epidemics of cholera."

**Germany.**

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 31st, 1901.

**THE SIGNIFICANCE OF THE SALTS AS REGARDS THE BACTERIAL ACTION OF SERUM.**

The *Zeitsch. f. Hygiene*, &c., has an article on this subject by Dr. v. Lingelsheim, from the investigations of

the writer it appears impossible that the effect of serum can depend on the osmotic process. The osmotic pressure is far too small to effect any considerable diminution of germs. In its qualitative aspect the serum action in the solution of cholera bacilli in rat serum is quite different from that occasioned by purely osmotic powers. All the conditions observed favoured the view that the bactericide power depended on special chemical substances nearly allied to the known ferments. One objection created some difficulty in an explanation, and this consisted in the fact already communicated by Behring that anthrax bacilli dried on silk threads grew and developed apparently without hindrance in active serum. A similar behaviour has been observed as regards bacilli contained in pledgets of lint, and the hypothesis has been brought forward that the serum cannot come into contact with the bacilli in the dried material and that the bacilli in the capillary spaces are less acted upon by the alexines. But all this cannot explain the fact that such bacilli grow in the presence of bactericide material. Experiments have led the writer to a more comprehensive explanation. The hypothesis of Fischer that the action of immune serum is attributable to an increase in the salts is in distinct contradiction to the elementary facts of immunity. The existence of bactericide ferment like active bodies in extra-vascular blood or serum can no longer be denied. Their relation to congenital natural immunity is still unknown for the reason that it is not known whether this material in its active state is contained in the living circulating fluids. The fact that they are in combination with certain specific immune bodies that come into action says nothing as to their behaviour with these bodies. Natural immunity no doubt depends on quite a series of components which may vary from case to case.

The *Archiv. f. Gyn.*, Bd. 63, contains an article by Prof. Kroenig on

#### THE PROGNOSIS OF ASCENDED GONORRHOEA IN WOMEN.

On the basis of his own observations the Professor comes to the conclusion that the prognosis of ascended gonorrhœa in the female is not at all unfavourable. The greater part of his thirty-eight cases of gonorrhœal adnexa disease recovered in a not lengthy period so far that pain no longer rendered them unfit for work. The treatment in the klinik was as follows:—If pain was great along with fever purgatives were given, generally saline, and ice bags were placed on the abdomen. No treatment was carried out per vaginam. After evacuation from the bowels, which was carried out to four to six stools per diem, the fever subsided in every case. With rest in bed the severe pains in most cases subsided. As soon as the symptoms subsided ichthyol tampons were inserted in the vagina, alternating with douching with hot water. In case of excessive hæmorrhage stypticine in three daily doses of 0.05 grm. was ordered, whereupon as a rule the hæmorrhage ceased. During treatment care was taken to avoid firm stools, fluid diet only was given. On discharge from hospital complete recovery had not by any means taken place, but the patients were quite capable of attending to their domestic duties. When the patients were treated as out-patients the treatment was the same, with the difference, however, that the measures could not be carried out so strictly. Want of the needful rest in bed was one cause of failure,

and also continued cohabitation on the part of the husband, even when strictly forbidden. This was a more disturbing factor than even continuance at work. But as a rule the polyclinic treatment was not longer than a few weeks, possibly partly for the reason that work at home prevented their attendance as long as was desirable.

Dr. Th. Neubiuger, Frankfort, has an article in the *D. Med. Woch.* on

#### THE RELATION BETWEEN SCLEROSIS OF THE CORONARY ARTERIES AND DISEASE OF THE CARDIAC MUSCULATURE.

His observations have led him to the view that the disease of the coronary arteries and the disease of the cardiac muscle caused by it develop in a certain and fixed manner, that they form a distinct clinical entity, and that the disease called angina pectoris is only a part of the complex of symptoms. The disease attacks men more than women, as a rule those of higher ages, and leads after months or years not unfrequently to sudden death. It may at times come to an apparent standstill, or recovery may be simulated.

The author distinguishes three stages in the development of the disease. The first he designates disturbance of sensibility, the second disturbance of motility, and the third disturbance of nutrition. In the first stage the patient complains of the well-known pains that cease on standing still or resting. As the disease advances the pain comes on on the least exertion or even when at rest, sleep is disturbed, and some patients complain of giddiness. After a varying length of time the second stage appears. The working power of the heart diminishes, the patient is easily tired, the breath is short, the pulse becomes small, empty and quick or abnormally slow. Percussion and auscultation reveal nothing abnormal, if there has been no previous valvular disease. This stage is not of long duration, and the third soon supervenes, that of disturbance of nutrition. The breath is short and superficial, the pains are more frequent and severe, the chest is affected, and thin frothy sputum is brought up, sometimes tinged with blood. The organic changes in the coronary arteries and in the fibres of the heart are so great that the heart ruptures. It rarely happens that patients in the third stage, after violent attacks, maintain their ground.

The treatment is that of heart diseases generally. Mental and bodily rest are essential. Nitrite of amyl gives passing relief, small subcutaneous doses of morphia are useful, and also the hypodermic use of caffein, sod. salicylate is to be commended. In case of lung stasis, digitalis given for three or four days every two or three weeks is useful. Dropsy may be suitably treated by diuretin. Mounting steps is injurious. Residence in high altitudes or on the sea is less to be feared. Syphilis and free living have no influence on the origination of the disease. Neither does valvular disease predispose to it. On the other hand, hereditary predisposition has a powerful influence. Among the 143 cases treated by the author, thirty of these were blood relations.

#### DEATH OF SURGEON-GENERAL VON COLER.

Dr. von Coler, the head of the Army Medical Corps, died of cancer on Monday week: he was born in 1831, and studied medicine at the Army Medical Academy in Berlin. He began his military career in 1856 as a

volunteer surgeon in the Dragoon Guards, and was appointed staff surgeon seven years later. He took part in the campaigns of 1864, 1866, and 1870-71, and distinguished himself so greatly during the operations that he was appointed as one of the first members of the medical section of the War Office, which was established after the end of the Austrian war. He played an important part in the reform of the Army Medical Corps, of the field and other military hospitals and the general sanitary condition of the army, and was subsequently appointed head of the Army Medical Corps.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 31st, 1901.

### NARCOSIS, OR ANÆSTHESIA.

The great ambition of the surgeon in modern times is to discover a narcotic or anæsthetic that will prove efficient and safe. To operate is now an easy and familiar art, but the performance without pain and yet secure safety is not quite so easy. Nothing in our armamentarium can surpass chloroform for efficiency, but its fatalities are on the increase. Schneiderlin proposed a form of narcosis by means of skopolamin hydrobrom with morphia, which he seems to have practised with considerable success. Korff now comes forward with a modification of this treatment and combines chloroform. His mode of procedure is first to clear the prima via. About seven in the morning of operation he orders a light breakfast of some fluid, at 8.45 he gives 0.004 gramme of skopolamin hydrobrom, with 0.01 gramme of morphia hydrochlorate subcutaneously; at 10.30, a second similar dose. If by this time the external reflex is not quite abolished a third dose may be given according to individuality an hour later, or about 12 o'clock. An hour after the last dose a few drops of chloroform are placed on an inhaler and administered in the usual way; only  $\frac{1}{10}$  or possibly  $\frac{1}{4}$  of the usual quantity is required to accomplish perfect anæsthesia. In eighty operations under this anæsthetic he had performed amputations, extirpation of mammary carcinoma with removal of glands from the axilla, gastrostomy, carcinoma of bowel, &c. The results were of the happiest kind, the patient resting quiet and calm after the operation.

### A CRYSTALLINE IMMUNISING PRODUCT.

Bordet was the first to draw attention to the immunising power of soluble albumen taken from an animal that had been previously immunised with blood serum, and that a precipitate could be obtained from the same blood by adding the same serum. In pursuing this experiment further Buchner and Jeret have found that a pure peptone, or the blood of the reindeer, can be acted on in a similar manner by the serum of the guinea-pig, which produces a crystalline precipitate with the property of a globulite. This globulite has an irregular round bean or kidney-like shaped crystal, strongly refracting light, and ranging in size from one to ten  $\mu$  in diameter, and very resistant to chemical agents. Its organic nature may be proved by origin, its behaviour with heat, and colouring with iodine.

### CHOREA AND ARSENIC.

Arsenic was recommended in cases of chorea by Comby

in such large doses that fatal results were often attributed to the drug and not to the disease. Although the drug has decided power in allaying the reflex action, it fell into disuse for a long time, till Bechterew awakened the old method by commencing with small doses and gradually increasing the quantity till very large doses can be taken with immunity, but never reaching a dangerous dose as Comby preached.

Bechterew also favours the use of bromide of potassium along with the arsenic, while salicylate of soda and cardiacs are also combined in many cases. In addition to these internal remedies he recommends hydropathic treatment, quiet in bed, and plenty of fresh air. Two weeks he considers the average time of treatment, although severe cases may be a month before convalescence sets in.

### MULTIPLE SCLEROSIS.

Gaup is in favour of injury being the real origin of this morbid transition. Anything that will injure the general system will affect the organism, disturb the sleep, and act as the initial factor in the nerve disturbance. Multiple sclerosis may be diagnosed if after an accident no cerebral or spinal effects seem to persist or remain prominent, but on the contrary a slow progressive development of the characteristic symptoms appears: For example a man falls five metres, and becomes unconscious, with pain afterwards in the occiput, more particularly on the right side, associated with the right foot, this being accompanied by vomiting. After this there is general pain, vertigo, with an easily tired feeling, an unsteady gait, weakness in the right leg, muscles of the neck, and a stiff feeling in the fingers. Next follow changes in the eye, the temporal papilla quadrant becomes white, the range of vision is narrowed, red and green are confused for one colour in the left eye, while there is increased tendon reflex and lowered cutaneous reflex. Along with these there is paresis of the muscles of the back and abdomen, and muscular groups of the lower extremities without spasms, although there may be distinct ataxia present. The paresis of the left side is usually greater than that of the right. The Romberg symptom is slight at first due to the paresis, while the ataxia and vertigo go on increasing.

Gaup considers the sclerosis commences first in the cerebellum from the tonus regulating function of the brain being early affected.

### DISINFECTING STATIONS AND TEMPORARY ISOLATION HOUSES.

THE threatened invasion of Europe by the plague is keeping the Continental medical world on the alert. The need of preventive measures is being pushed before Governments and Legislatures, while administrative sanitarians are doing their best to perfect national sanitary defences. The necessity for providing means to insure disinfection of houses in which zymotic diseases had occurred has long been recognised. Paris possesses a decidedly efficient Services des Etuves Municipales, which is divided into two branches (1) Stations where bedding, household linen, clothes, &c., are disinfected by steam under pressure; and (2) domiciliary disinfection of walls, floors, furniture, &c., by means of a spray of corrosive sublimate at a strength of one in the

thousand. At Berlin, house disinfection following many diseases is compulsory, and is carried out by the municipality. The means employed are: For bedding, household linen, and wearing apparel, steam at 212° F., under pressure; for the houses, rubbing down the walls with bread cut in large lumps, followed by a thorough sprinkling of carbolic acid at two and a-half to five in the hundred. Other municipalities carry out similar duties more or less systematically and stringently. But it was felt in some quarters that these precautions were not sufficient, as enormous difficulties arose in practice where poor folks lived crowded together in one or two rooms. Hamburg, we believe, was one of the first Continental cities to organise a disinfection and temporary isolation station on a large scale. The institution is meant both for townspeople and the seafaring classes. The whole station is arranged on the dual system: entrance section for suspected goods and individuals, and exit for the purified. In this institution poor people are received, their property disinfected, they themselves brought under the beneficial influence of baths, &c. While they are kept under observation for a day or two, their rooms are thoroughly disinfected and cleansed. In this way efficiency is attained with the least possible hardship to the people, and really at very little expense to the municipality. This system has been boldly adopted in Belgium, and Dr. Alfred Fillasier, of the Préfecture de la Seine, has written a most interesting pamphlet on "Les 'Postes Sanitaires' dans les Grandes Villes," in which he gives valuable details of this branch of municipal sanitary work. At Brussels, the "Poste Sanitaire" has been at work for some years, doing excellent service. The building consists of a ground floor and first floor. On the ground floor are the rooms for the attendants, w.c.'s and spray baths. On the first floor are found a dormitory with nine beds, lavatory, bath-room, and refectory. Persons brought to the station are conducted direct to the spray baths, and then to the dormitory. Meanwhile the clothes are disinfected, and their homes cleansed. Usually the next morning they are given a light breakfast, their clean clothes are returned, and they are at liberty to return home. The whole cost amounts to about 1s. 8d. per head per night. Antwerp possesses two similar stations, capable of receiving respectively seventeen and eighteen persons. The cost of the two stations for 1900 was under £300, including dinner, supper, and breakfast for each inmate. It is found that by these means domiciliary disinfection can be effectively carried out, at little trouble to those most interested, while people who could with difficulty be reached otherwise are brought under the control of the sanitary authorities. Thus greater efficiency is attained than if merely the sufferer from an infectious disease was treated at an isolation hospital. The system is so simple and free from hardships that persons of the poorer classes quickly recognise its value, and voluntarily submit to the sanitary authorities, as they see that by following this course they obtain greater personal security, and are not inconvenienced by the house-cleansing processes. M. Fillasier is anxious that "Postes Sanitaires" should be established at Paris, in order to complete the present disinfecting service the work of which, although carried out as systematically as possible, is often rendered nugatory

to the difficulty of cleansing a single room occupied by a whole family, who have nowhere else to go. It is claimed that such a step will be absolutely necessary if the recommendations of the Commission de la Tuberculose are adopted, in order to insure thorough disinfection of rooms and persons brought under the deleterious influence of consumptive patients. Such stations are also invaluable at maritime ports, as they are so easily managed at very little expense, and do not involve the hardships connected with isolation hospitals. It is also to be observed that municipal "Postes Sanitaires" as here described would greatly lighten the work of Port-sanitary authorities, and being under municipal supervision and frequented by ratepayers would not be so liable to the slovenly, and too frequently most insanitary, management of purely quarantine stations. Undoubtedly these "Postes Sanitaires" are admirable adjuncts to isolation hospitals, completing the sanitary circle at little cost, and at practically no inconvenience to the working classes, who are mostly concerned in the matter. Indeed, if all circumstances are borne in mind, the system means economy to municipalities and to citizens, as the figures and statistics in M. Fillasier's pamphlet so clearly demonstrate.

#### HEALTH MATTERS IN SALFORD.—ANTI-DIPHTHERITIC SERUM.

THE Annual Report of the Hospital Department of the County Borough of Salford for the year 1900 contains references to many points of general interest concerning the public health.

Like all such reports, statistics in tabular and schematic form occupy a considerable portion of the book.

The great question of "return" cases is touched on, and the erection of convalescent pavilions is considered to add "another line of defence to those already existing between the public and the recurrence of infectious disease, more particularly because more necessary in scarlet fever." It has been pointed out elsewhere that convalescent pavilions probably lessen also the liability to early second attacks in the same individual. The medical superintendent, with admirable foresight, and, we think, with great justice, warns his readers against expecting that even with the most carefully arranged system of convalescent pavilions, cases, apparently "return," will cease entirely to appear.

The infectious diseases principally dealt with in the report are scarlet fever, enteric, and diphtheria.

Of scarlet fever cases 1,328 were admitted with a mortality of 7.5 per cent. The average number of days spent by each patient in hospital was 44.7. This period will appear to some readers a somewhat short average time for isolation. The number of cases of enteric admitted were 216, and the percentage mortality was 25.0. The daily average number of days spent by each patient in hospital was 29.6. This will also appear to some remarkably short, especially in view of the fact that the percentage mortality was as high as 24.2. Of course, it must not be forgotten in this connection that many of the deaths among enteric cases in hospital occur shortly after admission.

The number of cases of diphtheria was 294, the percentage mortality was 24.2, the daily average number of days spent by each patient in hospital was 19.9.

The medical superintendent says:—"I have no hesitation in asserting that such heart failures, or any of the sequelæ of diphtheria, are from my experience unaffected by the use of anti-diphtheria serum." This opinion is the result of his experience of previous years as well as that of last year. He urges the importance of exhibiting this remedy as early as possible in doubtful cases as well as in certain cases of diphtheria. We may point out that in Liverpool the five fever hospitals in the city are used as depôts from which practitioners may obtain gratis a supply of serum at any time, day or night, for the use of poor patients.

"During the past twenty years," the report says, "only three members of the hospital staff have contracted diphtheria, while twenty-three contracted enteric. As no mention is made of it, it must be assumed that anti-diphtheria serum was not used as a prophylactic measure.

It seems a pity that the bacteriological work, for the efficient performance of which the superintendent acknowledges his indebtedness to his assistant medical officer, Dr. Pringle, has not been given more space in the report. More particularly would one appreciate bacteriological details in connection with the report on the use of anti-diphtheria serum in the treatment of "secondary malignant sore throat" among the scarlatina patients, which is said to have been attended by very marked and gratifying results. In fact, not one death has followed this "complication." It is not noted whether bacteriological examination of the throat is made preparatory to the patient's discharge from hospital. It would be interesting if in future reports a table were included showing the ratio of cases admitted to the total notified.

The medical superintendent, Dr. J. W. Mullen, is to be congratulated on his report; the arrangement of the matter makes reference easy and rapid.

## The Operating Theatres.

### GUY'S HOSPITAL.

**NEPHRECTOMY.**—Mr. ABBUTENOT LANE operated on a woman, æt. about 30, who had suffered for a considerable period from constant pain in the right loin, which was greatly aggravated at times when her abdomen became distended; the belly was tender, so that she could not bear the pressure of her garments. The swelling and pain diminished slowly, and this subsidence was associated with the passage of a quantity of milky urine. She consulted a medical man who found a tumour in the right loin which he took to be renal. The urine was loaded with pus; it had been examined for tubercle, with a negative result. A radiograph was also taken, but it showed no evidence of stone. When she was admitted into the hospital the condition was practically the same. The right kidney was very much enlarged, its surface was lobulated and firm; pressure on it produced great pain. The ureter was not enlarged or thickened beyond the normal. A further examination with the X rays showed nothing definite. The fact that the ureter was normal as far as could be detected suggested some cause other than tubercle. The kidney and ureter were freely exposed by a long oblique lumbar incision. The latter was perfectly normal to within one inch of its upper limit, where

it entered an inflammatory mass, which was inseparable from the kidney. With much difficulty it was partly cleared, when a small hard, nodular lump was felt. It was very cicatricial, dense, and the lumen of the ureter was clearly constricted irreparably; besides this the kidney substance had been subjected to much prolonged pressure; it was therefore felt to be hopeless to do anything but remove the damaged organ. This was carried out. When the indurated mass was examined it was found to consist of a small stone no bigger than a pea lying in an ulcerated thick walled cavity formed by the upper limit of the ureter. This was surrounded by the dense cicatricial inflammatory material already referred to. The conditions present were such that at this stage of the disease it was evident there was no possible treatment other than that of nephrectomy. This case illustrated very well, Mr. Lane said, the fact that the negative evidence of stone in the radiographic picture, however perfect, does not necessarily eliminate the presence of a small stone, indeed, frequently of one of a fair size. It also illustrated the fact that a very small stone may stick in the ureter, and that it may produce very much more damage to the kidney than one much larger in size in the pelvis. Mr. Lane also urged the importance of examining the ureter thoroughly in every case of obstruction to the flow of urine from the kidney.

### NORTH-WEST LONDON HOSPITAL.

**REMOVAL OF SUPPURATING CHOLESTEATOMA.**—Mr. TEMPLETON operated on a boy, æt. 16, who had been sent up to him by Dr. George Cathcart. The patient was suffering from headache accompanied by pain behind the left ear, with a history of discharge from the meatus on and off for two years. About ten days before admission a swelling commenced to appear behind the ear, which slowly increased, the skin becoming red and oedematous and the headache gradually getting worse; the temperature was 102, and the boy was in a dull sleepy state. There was no facial paralysis and no enlarged glands at the angle of the jaw. The discharge from the ear was slight and not offensive. The ear itself was stuck out, and, owing to the displacement of the pinna, had the characteristic appearance seen in cases of acute mastoid disease. On inspecting the membrana tympani the edges of the small perforation seen were quite healthy. Mr. Templeton said it was rather a curious point that there was so little discharge, and that even this small amount was not offensive, this being, he thought, rather a contra-indication to mastoid diseases. An operation was deemed advisable, and was performed at once after admission. After the part of the scalp adjacent to the ear had been shaved, a curved incision was made a quarter of an inch behind, and parallel to, the pinna; almost immediately under the skin a quantity of pus (three or four drachms) welled up; the mastoid process was then fully exposed, and the portion of bone superjacent to the antrum carefully cleared. Part of this formed the floor of the abscess cavity before opened. The periosteum and other materials were next cleared away with an elevator, and then a small yellowish bulging was noticed in the position of McEwen's triangle. The opening was therefore cautiously enlarged by a gouge, and a small quantity of this yellowish stuff taken up with a spoon. It was found to consist of the putty-like material characteristic of a cholesteatoma. The opening was now still further enlarged, and the

tumour, the size of a large filbert, was lifted up with its capsule and easily removed, the capsule separating from the adjacent bone without difficulty, there being no adhesions of any moment. There was, of course, considerable absorption of bony tissue from pressure of the mass, so that the upper portion of the tumour was in contact with the dura mater, therefore great care had to be exercised in cleaning out the cavity; this was done by first mopping it out, and then thoroughly irrigating it with 1-40 carbolic lotion. The tympanum was not interfered with by scraping through the external meatus, as there had been so little evidence of disease in the middle ear. The cavity was packed with iodoform gauze; a few stitches were placed in the upper part of the wound, the lower part being left open so that subsequent dressing could be applied. Mr. Templeton thought the interest in the case lay in the fact that it closely simulated an ordinary one of acute suppurative of the mastoid; the absence, however, of any offensive discharge, he pointed out, was somewhat in favour of cholesteatoma; the pain, too, had not been very acute. This kind of tumour, he said, was very uncommon. The growth itself, he remarked, was very easy to shell out, in fact, it came away quite in the same manner as an ordinary sebaceous tumour.

The patient was discharged in about a fortnight, and sent to a convalescent home. Only a small sinus remained, and all symptoms were quite relieved.

WEDNESDAY, SEPTEMBER 4, 1901.

#### TOWN CHILDREN AND HOLIDAY FUND INFECTION.

THE risk of catching infectious disease is never altogether absent from children who are taken for their summer holiday to a health resort. To a great extent parents and guardians are at the mercy of the lodging-house keepers and the sanitary authorities of the district they have elected to visit. On the other hand, of course, it happens not infrequently that reckless and selfish persons convey the germs of active infection hither and thither in the

persons of sick or convalescent children. But apart from these dangers, which are by the nature of the case restricted to the well-to-do classes, there has of late sprung up a separate and peculiar danger that demands careful consideration in the interests of the community at large. As happens in not a few analogous instances, the evil is wrought by want of head rather than by want of heart, a fact that will be at once apparent to readers when they learn that it is due to the philanthropic effort to send the slum children of our towns for a short holiday in the country during the summer months. A moment's consideration will show that in the absence of efficient medical supervision at each stage of the sojourn the door will be thrown open for the mutual conveyance of infectious diseases of all kind between town and country. The risk is clearly just as great for the country folk as for the citizens. The children sent out are obviously at an age and of a class predisposed to infection, and under ordinary arrangements they are distributed among cottagers whose chief claim to selection is the fact that they themselves possess a family of companionable age with that of their guests. Under such circumstances the town children's holiday movement, unless under rigid medical control, becomes practically an ingenious plan for maintaining the incidence of communicable maladies upon town and country. The principle of this philanthropic movement is above reproach, and it would be a thousand pities were the town children to lose their holiday for want of a little organisation. The question is purely medical and it seems one that should be to a great extent settled by the medical officers of the districts involved. A medical certificate of freedom from communicable disease of any kind, including not only the more commonly recognised specific contagious diseases, but also those of skin, eye, and scalp, should be exacted in the case of each child. A similar certificate should be required of the families visited. Arrangements should also be made for the systematic medical supervision and care of the town children during their absence. In a recent case one of these unfortunate holiday charges was sent back to town in a dying condition suffering from acute abdominal complaint, for which he had received no medical attention in the country. It need hardly be pointed out that all medical certificates and supervision should be paid for and be made a part of the cost of the funds. There is no reason, so far as can be seen, why a special tax should be laid upon the services of members of the medical profession any more than upon the railway companies or the caterers who are employed by the managers of the holiday funds. There is another aspect of this particular branch of philanthropic work with which as a medical journal we are not closely concerned, but which is almost precisely analogous with the intercommunication of bodily infection, namely, the moral damage likely to ensue from planting a number of children bred in

the slums among those who have been reared in the purer and simpler atmosphere of the country. That is a matter, however, for the consideration of those who devote themselves to the ethics of practical life, and we may look to them with confidence to treat the subject with the caution and sense of responsibility that it demands. From a medical point of view, we have felt it our solemn duty to dwell upon the dangers that are inherent to an essentially benevolent scheme. There was never any period in the history of preventive medicine when the necessity of joint action between urban and rural sanitary authorities in the prevention of infectious disease was more fully recognised. In our opinion, it would not be impossible to safeguard the organisation of the Holiday Funds in a satisfactory manner, chiefly by way of stringent medical supervision, and perhaps, secondarily, by an extension of the camp as against the boarding out system. In any case, it is to be hoped that by next summer some well-considered plan will have been framed to meet the exigencies of the present situation.

#### COXALGIA.

To the patient and intelligent study of M. Ollier, of Lyons, we are principally indebted for our knowledge of the pathology of coxalgia. We well remember the earlier pathology that saw nothing but an inflammation, and combatted the disease by killing the inflammation by exciting a greater one. The surgeon gave his whole attention to drawing out the inflammation, and blisters, setons, caustics—actual and potential—were used as the poor sufferer lay a willing victim to the well-intentioned but torturing attempts to kill the disease. Lucky was the victim who lived to afterwards go about on crutches, with the injured limb a useless appendage. Later the joint was cut down on, the bag of pus the capsule held was opened, and the head of the femur excised. It was as a treatment a distinct advance on the older method, and was the first-fruits of the new pathology. Months of suffering were saved to the patient, and the limb was neither so useless nor deformed as by the other treatment. Immobilisation of the joint and good feeding, with outdoor exercise, may fairly be claimed as a natural outcome of the recognition of the tuberculous character of the disease. And when commenced in the earlier stages the results obtained were excellent. Unfortunately patients did not come under treatment in the first stages of the disease when the apparatus and the constitutional treatment offered a chance of an arrest of the disease and the full use of the joint. Yet even in advanced cases progress was marked—a limb of the normal length without deformity, and, though stiff, more comely and useful than a crutch. The great drawback to this immobilisation treatment was the apparatus; as a rule they were costly and cumbersome; badly borne by children and young adults, and if not re-adjusted at short intervals more injurious than bene-

ficial. Where, to secure immobilisation, the child is placed on a bed and the limb extended by weights attached to it, the child suffers from the loss of outdoor exercise, and is liable, lying immovable, to all forms of chest troubles. If brought out on a reclining couch the risks of pulmonary disease are increased. The desideratum of the surgeon—fixation of the joint with mobility of the limb from the hip down—was not secured. To meet the want, M. Paul Archambaud has, especially in the case of infants, recommended an apparatus (*La Revue Médicale*) by which he hopes to secure correction of deformity, immobilisation of the joint during exercise, restoration of the muscular vigour and functional activity of the articulation, and facilities for general treatment. His lines of measurement are from the anterior spine of the ilium to the superior external border of the patella of the same side, and from the anterior superior spine of the ilium to the tuberosity of the ischium; and from the ischium to the patella as above. By drawing a base line from the anterior superior spine of the ilium to the tuberosity of the ischium a base line of an acute triangle is formed, whose apex reaches to the superior border of the patella. Made with adhesive plastic material this immobilises the joint and yet allows of exercise. To secure good results both sides are bound by the apparatus. We hope the results may equal the author's expectations; but we confess to a certain amount of scepticism of new apparatus for the hip joint. Since our early student days we are familiar with new apparatus for fractured clavicle new splints for Colles' fracture, and new methods of immobilisation of the hip-joint. An apparatus to secure the advantages for the patient that M. Paul Archambaud claims his will give is much to be desired, and we wish the distinguished surgeon every success in his attempt to improve our treatment of coxalgia.

#### TREATMENT OF ACCIDENTS UNDER CHLOROFORM.

THE treatment of accidents under chloroform is a question full of interest to most medical men, and one, too, on which all who undertake to administer the drug should have formed some definite opinion. In the recent numbers of the *Manchester Medical Chronicle* Mr. Wilson, Administrator of Anæsthetics, Royal Infirmary, Manchester, endeavours to classify the different accidents which are likely to occur, and to consider the mode of action and range of utility of the various remedies which have been suggested. The three classes which he adopts are shortly:—

1. Irregular and uncontrolled action of muscles during the stage of excitement.
2. Paralysis or loss of tone of muscles altering the patency of the respiratory passages and so causing mechanical obstruction to the breathing.
3. Specific paralysing action of the drug on the fundamental nerve centres in the medulla.

It is obvious that few cases of danger can be allocated to any one of these classes, for even presuming that the danger arises at

first from the irregular action of certain muscles interfering with respiration, still what makes this really serious is the danger of the sudden onset of the specific paralyzing action of the drug on the medullary centres. It is probable that any classification of accidents would be open to similar objections, but if it enables the administrator to grasp more clearly the general principles of danger it must be considered to have answered a useful purpose. The indications for treating these accidents are three-fold — to remove the anæsthetic-laden air from the lungs, to encourage the flow of blood to the nerve centres, and to stimulate the circulation and respiration. The various methods which are used to attain these ends Mr. Wilson groups into five classes—1. External reflex respiratory stimulants; 2. Direct mechanical or electrical stimulation of the heart; 3. The mechanical performance of natural functions such as artificial respiration; 4. Mechanical measures designed to counteract the effects of the failure of the circulation by raising the general blood pressure; 5. Drugs administered to stimulate the depressed nerve centres. Of the first group, the best that can be said is that they do no harm unless persevered in to the detriment of more important measures, and of the second, that they are either impracticable or positively harmful. Faradic stimulation of the precordial area, if any of the current reaches the heart, probably inhibits its action. Acupuncture of the heart is equally useless, and direct manipulation of the heart after opening the heart-chest is a remedy which requires more evidence of its utility before it can be recommended. Mr. Wilson believes that as good, if not better, results, can be obtained by intermittent pressure on the chest wall, accompanied by alternately raising and lowering the patient so as to empty and fill the heart. The difficult question has first to be decided whether the circulatory failure is the result of paralytic dilatation of the heart, or of paralysis of the vaso-motor mechanism. The methods of treatment suitable for each of these cases are absolutely antagonistic, and it is by no means easy to say which is the cause in any given case. It would appear that sudden failure of the circulation, accompanied by pallor of the face, and accelerated or gasping respirations denotes vaso-motor paralysis and requires inversion of the patient with pressure on the abdomen. On the other hand, if the dangerous symptoms are preceded by struggling, and the face is suffused, with signs of venous engorgement, the patient should be alternately raised to nearly the vertical position in order to empty the heart, and then returned to the horizontal position. Artificial respiration should be systematically persevered in in each case. If there is actual failure of the circulation little that is useful can be done by efforts to raise the blood pressure by such means as transfusion, &c. The same objection also applies to the use of drugs. Where there is failure of the respiration or circulation the difficulty is to get the drug to the nerve centre which it is to

stimulate. In those cases in which this can be effected hypodermic injections of strychnia and the extract of suprarenal capsule, with inhalation of ether, are probably the most useful.

## Notes on Current Topics.

### The Duration of Pregnancy.

It would seem that in the human organism those phenomena which are of the most everyday occurrence are usually the most difficult to explain. A concrete example of this is given by the various phenomena of pregnancy. Pregnancy is, one would think, a sufficiently long-established condition to enable us to understand something about it, and yet our ideas on many points connected with it are of the vaguest description, and our definite knowledge practically non-existent. When does impregnation occur? Where does impregnation occur? What are the causes of the onset of labour? What is the exact duration of pregnancy? and, Is there a fixed period for gestation? Perhaps the most practically important of these questions, not alone to medical men but also to the legal world, are, "What is the duration of pregnancy?" and, "Is the period of gestation capable of variation?" Of course the time which is usually fixed in the medical and lay mind is a period of ten lunar months, or nine calendar months, or 280 days. The statistics of Loewenhardt, Hasler, and Hecker, obtained from the records of a large number of cases in which pregnancy resulted from a single coitus, gave an average duration of from 272.2 to 273.5 days, a period which is somewhat shorter than the popularly accepted one. Perhaps the latest statistics on this interesting subject are to be found in a recently published article by F. von Winckel. The writer considers that as the methods of estimating the length of human pregnancy hitherto proposed have proved unsatisfactory, the important question whether a pregnancy had been unduly prolonged might be better determined by estimating the length of the gestation of abnormally large and heavy children at birth, and comparing this with the average duration of pregnancy in all uninterrupted cases. During the thirty years he had charge of the clinic at Dresden and Munich he met with 1,007 children over 4,000 grms. when born. Only five were over 5,000 grms., and the heaviest was 5,320 grms. v. Winckel draws a series of conclusions of which the following are the most important:—Prolongations of pregnancy, that is to say, delayed labours, undoubtedly occur; important evidence of their occurrence and of their frequency is given by the number of children which at birth weigh 4,000 grms. or upwards; the frequency of such children in large clinics amount to 3.15 per cent., and about 14.5 per cent. of them have been more than 302 days in the uterus. The frequency of delayed labour is 2.8 per cent. The proofs now advanced that so many children (14.5 per cent.) remain more than 302 days in the womb shows that this, the German limit of legitimacy, is too low.

### Ovarian Extract.

THE trend of modern therapeutics has of late been in the direction of organo-therapy. In most cases glands with external secretions contain a member of the group of ferments, but in the case of the internal secretions of glands the product is usually of a complex substance, and it is exceptional for it to be of the nature of a ferment. Thyroid extract, orchitic extract, and supra-renal extract, together with ovarian extract, are among the latest additions to the list of therapeutic agents. The reason underlying the administration of these extracts is the undoubted fact that diseases may be caused by interference with the activities of these glands. In the case of ovarian extract an extremely interesting report has just been issued by Dr. Krusen in the Johns Hopkins Hospital *Bulletin*, in which he gives his experience for the past three years of the use of this extract in amenorrhœa, in dysmenorrhœa, in those suffering from symptoms following the removal of the uterine appendages and for the disturbances in connection with the menopause. The conclusion arrived at is that the theory of the use of this extract is faulty, and its administration based upon a wrong assumption as to the function of the organ. This is quite in agreement with the views of many authorities on therapeutics, but it is certainly reassuring to be told that the extract is practically harmless. In those cases where relief has been noted it is questionable whether the improvement was not due to mental suggestion, and it is quite evident that no definite reliance can be placed upon the preparation.

### A Penny a Week for the Doctor.

EVERY now and then the medical world receives a sharp reminder that Nemesis sits behind their want of business method. Sooner or later the reduction of fees that has resulted from unworthy competition educates the public into the belief that all medical advice should be obtainable at a low remuneration. The tendency then naturally arises to cut down salaried appointments, an occurrence that is reported almost every day of the week in various parts of the United Kingdom. An instance of this grinding economy was shown last week by the Mile End Board of Guardians. That body has taken the progressive step of boarding their Poor-law school children out in scattered homes. When the question of medical attendance came under discussion it was reported that some medical men had agreed to attend when necessary, and to supply medicines and dressings at sums varying from sixpence to threepence per week per child, while one doctor tendered at twopence. Even the last-mentioned offer failed to secure the acceptance of the guardians, who have deferred the matter to a sub-committee, on the ground that the "figures were too high." One of them said that he paid only a penny a week for his doctor, a statement which appeared not to have caused him any shame or compunction. Clearly, medical men have themselves to thank for the

diminished estimate of their public worth by attaching so low a value to their services to clubs and medical aid societies, to say nothing of other kinds of cheap and gratuitous work.

### Fatal Treatment of Aneurism by the Gelatine Method.

TWO cases of considerable medical interest were investigated last week at Guy's Hospital by the City of London coroner. As most of our readers probably know, a new method of treating aneurism by the subcutaneous injection of gelatine has recently been introduced. One of the house-surgeons at Guy's, Mr. L. Stamm, had three cases of thoracic aneurism under this specific treatment. He himself sterilised the gelatine, of which several ounces were injected into the leg or other part of the body, so as to enter the general circulation, where it increases the coagulability of the blood and so leads to the consolidation of the sac. Of the three cases thus treated one was discharged cured, while the two others developed tetanus and died. There can be no doubt that the specific organism of tetanus was introduced along with the gelatine. This accident is most unfortunate, as it will tend to cast a stigma upon what is undoubtedly a valuable scientific method of treating an incurable disease. No blame can be attached to the house surgeon, who had taken every precaution possible from a human point of view. The treatment was first introduced by Lancereaux, of Paris, who administered every six or eight days four to five grammes of gelatine in two hundred cubic centimetres of 0.7 chloride of sodium solution. If properly sterilised there should be local reaction at the point of injection. Lancereaux reported five cases of aneurism, of which three were cured. It is therefore obviously unfair for the newspapers to speak of the method as hospital experimentation upon patients.

### Anti-Vivisectionists, Take Note!

THE worthy folk who refuse to sanction experimental inquiry into physiology and disease in the lower animals must find plentiful matter for wringing of hands in the busy universe of science. Pathological laboratories are being daily added to all our large general hospitals, where technical vivisection is carried out on a large scale in order to discover what is the exact nature of the maladies from which patients are suffering in the wards. To take an example: a patient is afflicted with some obscure lung complaint, as to which prolonged and careful observation has failed to form a decided diagnosis. A portion of his sputum is inoculated into the tails of a couple of white mice, or under the skin of two or three guinea pigs, and it is noted whether the animals recover or die, and if the latter, whether they succumb to pneumonia, tubercle, or some other disease set up by known micro-organisms. The verdict thus obtained, due technically to vivisection, is clearly of vital importance to everyone concerned. On the one

hand it may carry the death warrant of the patient, or, on the other, may determine a course of treatment which will end in his complete recovery. Without a biological test of the kind in doubtful cases no physician could sincerely say he had given his patient the fullest advantages afforded by modern scientific medicine. The matter, therefore, resolves itself into a direct balancing of the lives of mice and guinea-pigs against those of our fellow-creatures. Which is to win? Medical men are on the side of humanity, on which side are the vivisectionists?

#### British Medical Association Meeting, 1902.

THE announcement has been made that the next annual meeting of the British Medical Association will take place at Manchester. As a busy Lancashire centre that town offers a considerable contrast from Ipswich and Cheltenham, the last two places visited. The population of Manchester is over 500,000, while its suburb, Salford, contains 198,000 persons. A large increase has taken place in this direction since the last visit of the Association some twenty-five years ago. The proportionate growth, however, has probably nothing like equalled that of the Association, which now reckons some 19,000 members. The President-elect is the well-known surgeon, Mr. Walter Whitehead, who has held many surgical appointments in the city, as well as the professorship in clinical surgery at Victoria University. The association of the place with a young and vigorous University will doubtless add to the brilliancy of the meeting from a scientific point of view. It will be of much interest to note the course of affairs now that the constitution of the Association has been so materially altered.

#### Medical Miracles.

THE fashion of the present day is to consider that medical miracles in the healing of the sick occur only with Christian Scientists or at Lourdes. The following two cases, out of others, are sufficient to show to all unbiassed minds that what may be justly described as miraculous cures occur now and then in patients under the care of duly qualified practitioners of medicine. The first case is given on the unimpeachable evidence of Dr. Osler, of Baltimore. A woman came to him with cancer of the breast, and on his advice it was thoroughly removed by Mr. Halstead. The prognosis was, of course, unfavourable, and two years afterwards she came again to Dr. Osler, suffering from sarcoma of the choroid. The patient went from bad to worse, and in June, before going away for his holiday, Dr. Osler went and said good-bye to her. She was then in great pain, secondary tumours had appeared near the breast, the liver was invaded, and she was paraplegic. A year later Dr. Osler was astonished to find that the nodules round the breast had gone, she had recovered from the paraplegia, and she was regaining vision in the affected eye. A short time ago this lady went two miles to the railway station to meet Dr. Osler. A yet more astounding recovery has been reported.

About four years ago Mr. Tiffany, a surgeon, removed at Dr. Osler's request a cancerous breast, and the case appears to have at first followed the usual course—that is to say, secondary growths made their appearance. About twelve months ago she was not expected to live, and she complained much of girdle pain, and pains down the leg, ultimately becoming paraplegic. The woman, however, did not die, but gradually improved and went away into the country. A few months ago this patient walked a considerable distance to see Dr. Osler, who found that she still had some secondary nodules and a certain stiffness of the back. She continues to take morphine, but gets about and attends evening parties and general entertainments of that kind. There is no desire on the part of the medical profession to put themselves into competition with the therapeutical agencies mentioned above, but it is well to remember that there is no monopoly even in so-called miracles.

#### Christian Science "Testimony" Meetings

THE *British Monthly* for September reports some astounding "testimonies of cures" said to be adduced at the meetings of this strange cult. "Were there no fools there would be no knaves" is a dictum more frequently exemplified in quackery than in aught else with which we are acquainted. Unfortunately there are always considerable numbers of emotional people with little to do, who are ready at any moment to be carried away by the latest craze. In this case we have educated and aristocratic people making themselves ridiculous in the eyes of their neighbours. They are a psychical study, and therefore the advice given in the *British Monthly* is worthy of careful consideration. It says: "If doctors of repute would attend the Wednesday evening testimony meetings, and talk privately with the men and women who describe these cures with such evident sincerity, they would be able to judge for themselves of the facts which at the present moment are so puzzling to inquirers. So long as the narratives remain unsifted, credulous and excitable people will, we fear, be more and more drawn into the ranks of the Christian Scientists." Quite recently an American physician offered a cheque for £200 to anyone who would bring forward convincing evidence of a complete cure being effected of any bodily deformity by the methods referred to. The issue may be awaited with confidence, for there is not the slightest risk of the depletion of the bank balance of the medical man in question by his apparently sporting offer. We would here draw the attention of the editor of the *British Weekly* and the *British Monthly* to the objectionable advertisements in journals supposed to circulate among clergymen. He there serves up as a literary hash from his own pen "The Religious Use of Memory," with advertisements inviting readers to a free trial of galvanic belts, free trials of cures to all the ills to which human flesh is heir; the "cure of consumption" by E. W. Alabone, &c., which make most unsavoury and questionable reading. Such advertisements do much harm, and yet they

continue from week to week and month to month. As the editor professes his anxiety to know the truth of the so-called "cures" by Christian Scientists he should give evidence of his zeal by taking care that his readers shall not be driven hither and thither by so many forms of rampant quackery. One at a time should be enough for their mental balance.

### Obesity and Politics.

ACCORDING to some lately published statistics the number of fat men counted in a first-class hotel, out of a total of 100 was seventy. The statistician is not so rude as to call these gentlemen fat or even to style them obese, he politely refers to them as men from the age of twenty upwards who showed an abnormal development in the abdominal region. It would further appear that these well-covered gentlemen included in the 70 per cent. united imperialistic politics with their inclination to *embonpoint*. The medical journal giving these figures infers, somewhat severely, that imperialism is usually obese in type. In a hotel frequented by the upholders of democratic principles the percentage of fat men was only eleven, and the conclusion drawn is that if democracy and radical ideas are to be maintained, careful heed must be taken to prevent any undue tendency to abdominal expansion. The energetic compiler of these statistics pursued his observations in a residential quarter where the dwellers were well known to hold imperialistic views and the percentage of fat men was 35; in a radical suburb, however, the percentage rates of obese personages was 14. It has not been attempted before to maintain a connection between obesity and imperialism by means of statistics, which are notoriously fallacious, but both among adults and children there is certainly an increase in the number of persons corpulent to the degree of deformity. It is generally supposed that luxurious and sedentary methods of life with over-indulgence in sleep and absence of mental occupation are among the recognised predisposing causes of obesity, and though it may be convenient to suggest the cult of imperialism as the cause, the true bearing of the figures cannot be overlooked that increased prosperity generally means increased self-indulgence with its attendant drawbacks.

### Surgical Interference in Appendicitis.

THE question of the surgical interference in cases of appendicitis is one which as yet can hardly be said to be satisfactorily settled either from the point of view of the physician or the surgeon. In the August number of the *Edinburgh Medical Journal* Mr. Walter Spencer helps materially towards its solution. Mr. Spencer classifies these cases clinically as follows: (1) Cæcal distension. In these cases the treatment is purely medical and the prognosis good. (2) Perityphlitis. This may yield to medical treatment, but if it produces adhesions they may necessitate surgical interference later. (3) Appendicitis proper, of which there are four varieties.

(a) Acute perforation in which early operation affords the only chance of success. (b) Suppurative appendicitis in which extra-peritoneal draining of the abscess should be done as early as the diagnosis can be made. (c) Relapsing and recurring appendicitis, which must be distinguished by careful examination after the attack, and if the signs of chronic appendicitis are found the appendix must be removed at once. (d) Chronic latent appendicitis with septic anæmia is the most difficult of all varieties to diagnose, and there is great danger that it will not be recognised till too late for useful surgical interference.

### Motoring versus Horse Exercise.

THE great Horse Show in Dublin last week at which there was so brilliant a gathering both of feminine and equine beauty, recalls the medical mind to a contemplation of the physical effects likely to compass future generations by the use or misuse of the vehicle which is to supersede the horse for locomotion and exercise. We believe that the old hygienic proverb "the outside of a horse is the best medicine for the inside of man," has been received within the canon. We may perhaps be permitted to add of our own personal inspiration that a thoroughbred woman seated on a thoroughbred horse represents the highest standard of human grace and dignity in physical exercise. With the growth and multiplication of the motor car one of the most telling factors in the production and maintenance of a perfect physique must necessarily dwindle more or less rapidly. Horse exercise will gradually become less immediately useful and less fashionable. The bicycle rider could say much in favour of his mode of progression, even although neither graceful nor dignified. Now we have the "motor," favoured by "business-men" because of its swiftness, and by snobs and *parvenus* because of its expensiveness. Its vibrations may recall to the memory of our readers the *chair* so ostentatiously used by the well-known French specialist in the treatment of some forms of nerve disorder, and the element of explosiveness may bring up recollections of the "earthquake treatment" of hysteria. That its discordant notes must modify the auditory and collateral centres is, we think, unquestionable. Accordingly, we fully anticipate the development of new features—some of them of a decidedly pathological tint in the future generations of the votaries of the motor car. Of course further progressive modifications may tone down or remove some of those features of its construction and action which we now feel least disposed to admire. That there are too many horses on the streets of our large cities must have been strongly felt by any person who lived in London during the burning days of the past July. So that the multiplication of motor cars will at least tend to lessen one of our substantial metropolitan grievances. Its early defects may be rapidly outgrown, like those of other infancies, under judicious culture, so that there may be hope for the

future of the "motor," although we confess, for the present, to a feeling of discomfort in that quarter.

#### The Certification of Lunatics.

OUR readers will recollect a resolution passed by the Belfast Board of Guardians on June 5th with regard to a change in the procedure at present adopted in certifying lunatics, in which, among other points, it was suggested that the Poor-law medical officer should be obliged to visit the supposed lunatic at his residence, and, from the results of that visit, issue a certificate of lunacy if necessary. For this task, the medical officer was to receive the magnificent fee of five shillings. We suggested at the time that such a procedure was illegal, and that it was doubtful if so radical a change could be made, and we are glad to find that the Local Government Board take the same view. It is unnecessary to dwell on the absurdity of the fee, or on the almost insuperable difficulties which would surround the medical officer in the discharge of such a duty. The following is the reply of the Local Government Board:—"The Local Government Board have had before them the resolution adopted by the Board of Guardians of Belfast Union on the 4th ult., respecting the procedure to be adopted in the removal of lunatics to the District Lunatic Asylum, and the Board desire to state that they are advised that the proposed arrangement could not be carried out under the existing law, because there is no legal duty as to the examination and certifying of lunatics other than dangerous lunatics imposed upon dispensary medical officers, and no legal authority to pay the fee or other expenses incurred out of the poor-rate. In these circumstances the Board regret that in the present state of the law they are unable to approve of the arrangement proposed by the guardians."

#### Post-mortem Risks.

THE increasing number of post-mortems that are now made both in this country and abroad is not unattended with certain serious risks, some of them capable of being easily prevented, others unfortunately, however, offering greater difficulties. A striking example of the latter type of danger is well shown in the account published by a Dr. Fuenrohr of his own attack of typhoid fever from infection to which he was exposed at a post-mortem on a case of enteric. The autopsy unquestionably was conducted with the most scrupulous attention to every precautionary detail, but the facts nevertheless point undoubtedly to the truth of the assumption that the fever was imparted to Dr. Fuenrohr at the examination of the body. The only explanation of the way in which the infection was carried is that during the process of rinsing the intestine with water, which he, as usual, effected by means of running water, small particles of virulent matter were splashed upon him. The possibility of this accident occurring is not sufficiently appreciated by those whose duty it is to conduct autopsies, and means should be devised to pre-

vent typhoid infection from this method of washing the bowel for the purposes of investigation.

#### Disreputable Advertising in "Reputable" Journals.

MANY of our home journals might with advantage copy the action which has been taken by the Philadelphia *Times*, under its new management, and which can be gathered from the following resolutions recently passed by the Medico-Legal Society of that city:—"Whereas, the advertising of abortionists and their drugs, as well as other disreputable secret medicines, has for years been a notorious disgrace to the newspaperdom of this city, an evil seemingly without redress, and, Whereas, the Philadelphia *Times* under its new ownership has declared for a high ethical plane, avoiding all sensationalism, while at the same time furnishing 'all the news that is fit to print,' excluding all medical and other questionable advertisements so as to make it indeed a newspaper fit for the family circle, therefore be it Resolved that the Medico-Legal Society of Philadelphia highly approves of the advanced stand taken by the *Times* and urges upon the medical profession generally its active support in aiding to carry out that journal's elevated ideals." There are papers in Great Britain also laying claim to the title "family" which are a disgrace to journalism and an insult to moral standards by reason of the advertisements they admit into their columns. We fear it is too much to hope that they will take a lesson from the foregoing until compelled by law to do so.

#### Pregnancy Following Myomectomy.

SOME years ago Dr. Alexander, of Liverpool, read a paper before the British Gynæcological Association on the removal of multiple myomata of the uterus by myomectomy through a single incision in the uterine wall. The operation was not received with any great favour at the time, as it was thought that the uterus after this proceeding would be so mutilated as to render its absence preferable to its presence. Accordingly, it is interesting to find that in the *Medical Record* for August 17th Dr. James N. West, in a paper records a case in which he removed sixteen tumours, through nine incisions, from the uterus of a woman on March 16th, 1899. On January 8th, 1901, he attended the same patient in her confinement, when she was delivered after a perfectly normal labour, lasting twelve hours, of a healthy boy weighing 7½ lbs. In spite of the extensive scars in the uterus the expulsive force was ample, and the only complication was a lacerated perinæum. Dr. West gives an interesting analysis of the recorded cases of pregnancy following myomectomy.

THE Society of Apothecaries, London, announce that the Gillson Scholarship in Pathology, value £90, will be open for competition in January next. Competitors must hold the L.S.A., or obtain it within six months after gaining the scholarship. Further particulars can be obtained of the Secretary to the Examiners.

**The Doctor in Fiction.**

It is apparently almost impossible for the writer of fiction to touch upon medical subjects without falling into error, and an exceptionally glaring instance is afforded in Mr. Hall Caine's novel, "The Eternal City," that has just been published. Chapter VIII. of the part of this work entitled "The Roman of Rome" describes how a medical man examines the breast of a patient and the glands under her arms, and, finding cancer, announces that a nurse must be summoned immediately. On the next page this practitioner, who is supposed to be the most costly and fashionable doctor in Rome, is made to tell the friends that if the cancer had been diagnosed earlier *nephrectomy* might have been possible, but that the case as he found it was beyond the reach of legitimate surgery. Mr. Hall Caine has portrayed in an earlier novel an impossible hospital nurse, but the medical man he has presented us with in "The Eternal City" is more impossible still.

**Are Rontgen Rays Infallible?**

A NUMBER of papers have been recently written concerning the fallacies and difficulties in the diagnosis of fractures by means of the Röntgen rays. A case has recently come under our notice which illustrates forcibly the difficulty in localising foreign bodies in the alimentary canal below the œsophagus. A patient swallowed a dental plate made of gold with two teeth attached. When admitted to hospital the plate had passed the cardiac orifice of the stomach. For three consecutive days an expert radiographer manipulating the most up-to-date apparatus failed with either fluoroscope or sensitive plate to demonstrate the presence of the denture, and this notwithstanding the fact that buttons, coins, and other objects could be distinctly seen through the whole thickness of the body. The peristaltic movements of the intestines would account for the failure in the case of the photographic plate, but it is difficult to understand how these movements would interfere with the view obtained by means of the screen.

**Inoculation in Enteric Fever.**

THOSE interested in the preventive treatment of enteric fever by inoculation are still looking forward to the results of the statistics on this subject which may be derived from the Army Surgeons in South Africa. The figures given by Mr. Andrew Balfour, late Civil Medical Officer, South African Field Force, in his paper entitled "A Ship of the Veldt," in the current number of the *Edinburgh Medical Journal*, are of great interest. The figures cover a period of five months, and are as follows:—

	Admitted.	Recovered.	Died.
Inoculated	92	89	3
Uninoculated	551	511	40
Died inoculation unknown			17
Percentage mortality of those inoculated,	3.25.		
" " of those not inoculated,	7.2.		

In all cases the diagnosis was confirmed by Vidal's reaction. and though the number of the cases is not sufficient to base any definite conclusions, still the results must be regarded as eminently satisfactory.

WE regret to learn that Dr. Alfred E. A. Lawrence, Professor of Midwifery and Diseases of Women in University College, Bristol, died suddenly on the 30th ult. while on holiday with his family at Bishop Steignton, Devon. He was supposed to be in good health when he left Clifton three weeks ago, and the news of his sudden death has been received with startling surprise and sincere regret in Clifton.

AT the meeting of the British Association for the Advancement of Science, to be opened at Glasgow on September 11th, Major Ronald Ross, I.M.S., will read a paper on "Tropical Parasitology."

MR. TREVOR N. SMITH, J.P., F.R.C.S.I., has been appointed Assistant Master of the Coombe Hospital, Dublin.

**Correspondence.**

[We do not hold ourselves responsible for the opinions of our correspondents.]

**VERATRUM VIRIDE IN PUEPERAL ECLAMPSIA.**

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your annotation on the value of *veratrum viride* shows the continued faith of American physicians in one of the oldest remedies for puerperal eclampsia. It was the remedy of the "medicine man" from Manitoba to the Gulf of Mexico, and its use by the Indians introduced it to the first settlers in the Colonies. As far back as 1849 Dr. Porcher published an account of its therapeutic properties, and soon afterwards Dr. Norwood, of South Carolina, published in the *Charleston Medical Journal* his formula for the tincture, which there is known by his name, and has been freely used throughout the United States. He recommended it to be given in "six to eight drop doses, repeated cautiously." I fear the dosage you mention, "fifteen to sixty minims of Norwood's tincture" every fifteen minutes, could not be taken, for such a dose would act as a powerful emetic and produce toxic symptoms of an alarming character.

Indeed, Norwood's tincture is so strong that it has been latterly displaced by one not half the strength. The *Am. J. Pharmacy*, N.S., iv., p.89, gave a formula for a tincture so weak that the ordinary dose was thirty minims.

The fullest account of the therapeutics of the drug is H. C. Wood's: "A contribution to the knowledge of the physiological action of the alkaloids, *viridia*, *veratroida*, and of the resin of *veratrum viride*," published in 1870, as a reprint from the *Am. J. Med. Sc.* He concludes that "*Veratrum viride* slows the pulse by a direct depressant action on the heart muscle, and by stimulating the pneumogastric nerves; it lowers blood pressure by action on the heart muscle and by depression of the vasomotor centre."

The more recent investigations by Dr. C. Briz are even less favourable to the drug.

Of its action on the heart he writes:—"At first there is a continuous stimulation and increase in the pulse-rate and in the blood-pressure. The duration of the contraction then becomes longer and longer, the rate being diminished to one-half owing to the duration of the systole. All parts of the heart finally become insensitive, even though it still contracts occasionally. atropine now produces no effect. The pulse-rate and

blood-presence gradually become less and less, and if artificial respiration has been maintained, death takes place from paralysis of the heart."

Veratrine, which Meisner discovered in the seeds of *cevadilla* in 1819, and in his description of it in 1821 was the first to use the word "alkaloid," is not found in the rhizome of either *veratrum viride* or *veratrum album*. The product obtained by M. M. Pelletier and Casenton, in 1819, in the root of *veratrum album*, was a mixture of *jervine* discovered by Semon in 1837, and *veratroidine* discovered by Bullock in 1865.

The last named alkaloid slows the pulse by stimulating the pneumogastric centres, and finally quickens it if given in very large doses by paralyzing the peripheral vagi. In toxic doses it causes purging and vomiting.

Jervin according to Hare, causes great slowness of movement, relaxation of the muscles, through which thrills continually run, and finally the animal falls to the ground. Violent epileptiform convulsions may now ensue, but no tetanus is present. The convulsions now give place to paralysis, and are characterised by their lack of force. Sensation is not affected until the near approach of death brings on anæsthesia.

The convulsions are due to the disturbance of the circulation at the base of the brain (Wood), and the spinal cord is directly depressed by the effect of the jervin on its motor tracts.

The tincture of the rhizome of the plant is the preparation generally used. In some parts of the Continent Norwood's tincture is the favourite, and his writings are favourably quoted by Dr. Gaetano Malacudd in his "Manuale de Materia Medica," 1896. The drug is also recommended by Dr. Larea z Cerezo in his "Diccionario de Medicina," 1894. In Germany it is well spoken of in the writings of Kocher, 1866, Liebmeister, 1876, and Pégaitar (*Arch. f. Klin. Med.*), 1869. Reference to its anti-pyrexial properties are frequent in French medical literature. Trousseau's recommendation of the *veratrum album* needs no repeating. I may just add that the chemical composition, *veratrum viride*, is closely analogous to that of *veratrum album*, and the specific distinctness of the American *veratrum viride* from the European *veratrum album* is very doubtful. Certain Alpine forms of the *veratrum album* are said to exactly resemble the *veratrum viride*.

I am, Sir, yours truly,  
F.R.C.S.

## Obituary.

### DR. H. C. BUCKLEY (KENSINGTON).

DR. HENRY CHILD BUCKLEY, whose death from heart failure has taken place, at the age of 57, at his residence, Linden Gardens, Kensington, was the son of Mr. James Buckley, of Penyfai, Llanelly, at one time high sheriff of the county. After going through his curriculum at St. George's Hospital, London, he obtained the L.S.A. and M.R.C.S., and subsequently he took the M.D. of Aberdeen University in 1868, and commenced practice in his native town of Llanelly, and was appointed medical officer of health, which position he held for many years. Possessed of ample means, he retired from practice in 1890 and left Llanelly to reside in London. On several occasions Dr. Buckley was asked to stand as a candidate for the Parliamentary representation of the Eastern Division of the county, and also for the Carmarthen Boroughs, but this honour, however, he firmly declined.

## Literature.

### LAWRIE ON CHLOROFORM. (a)

It seems paradoxical that anæsthetics should excite passion and stir up strife. But from the first it was so. Edgeworth, Southey, Coleridge, Davys, and Beddoes had

(a) "Chloroform; a Manual for Students and Practitioners." By Edward Lawrie, M.B. Edin., M.R.C.N. Eng., Lieutenant-Colonel I.M.S., Residency Surgeon Hyderabad, Principal of the Hyderabad Medical School. London: J. and A. Churchill. 1901.

just tested the properties of nitrous oxide gas, and Count Rumford was securing Davys' services to popularise it and other chemical discoveries, when Mitchell uttered his warning that nitrous oxide was a lethal agent and should be banished from the laboratory and the lecture room.

A whole library of books tell of all the heart-burnings that followed on Crawford W. Long's introduction of ether as a general anæsthetic, even Simpson's introduction of chloroform called forth the Waldie and other controversies.

But worst of all came the heated discussions that followed each attempt to learn the physiological action of the different anæsthetic agents. The interpretation of each fact was disputed with a warmth of feeling and a lack of courtesy quite out of place in considering a scientific question, and such as we associate with religious controversy alone.

Dr. Lawrie's book keeps clear of controversy, though he finds it necessary in the introduction to recount the circumstances that led to his series of cross-circulation experiments, and to print Dr. W. H. Gaskell's letter telling why Dr. Gaskell and Dr. Shore's experiments failed; the ligature which Shore tied at the time of establishing the cross-circulation "was not tight, so that the injection was able to pass both into the vertebral and into the arm on that side."

The book is divided into five parts and an appendix; in the first part the author considers the physiological action of chloroform; in the second he deals with the application of the physiology of chloroform to practice; in the third he considers how to give chloroform; in the fourth he gives his clinical observations; in the fifth he details a few original experiments made in Hyderabad to illustrate the points in the physiological and clinical portions of the work.

The book to the student of medicine—and every member of the profession worthy of the name is a student of medicine—is worthy of attention and careful reading. It is the outcome of years of study by one who possesses the intuition of Claude Bernard as an experimentalist, the dexterity in carrying them out and the capacity of making them intelligible of a Hunter. We have had many books on this subject—books that told of the industry of the compilers, and were creditable as evidences of the author's familiarity with the literature of the subject, narratives of long and fruitless physiological experiments, on frogs, amoeba, dead tissue, and so forth—labours as useless for scientific purposes as those of the philosophers of Laputa. We have read of instances of anæsthesia in many varying compounds that might one and all have been made by any druggist's assistant, and we have books made up of such *olla podrida* occupying our shelves. They reflect no credit on British medicine; they in no way advance science; they contribute nothing to our stock of knowledge.

Standing apart from these, different with the difference born of genius and originality, are the works of Snow and Lawrie. Their works are as a bright light in a dark place, they make clear the path, they point out the safe road that scientific knowledge has traced for the guidance of all who desire to follow. Since Snow's book appeared no such valuable book on anæsthetics has been published as Dr. Lawrie's.

### PAKES' HYGIENE. (a)

THIS book is the most complete laboratory guide to public health work hitherto published. Its author has gained the necessary experience for teaching purposes as bacteriologist and demonstrator of sanitary science at Guy's Hospital. His aim has been to treat the whole of the practical work required for a public health diploma. He has divided his subject into five sections, namely, bacteriology, microscopy, chemistry, physics, and vital statistics. Under bacteriology is given a concise description of the more important bacteria and the method of their examination. The section of microscopy is particularly

(a) "The Science of Hygiene." By Walter C. C. Pakes, D.P.H., F.C.S., Bacteriologist and Demonstrator of Sanitary Science, Guy's Hospital, &c. London: Methuen and Co. 1900. Price 15s.

full and will be found of special value to the student who is preparing for examination. There are numerous illustrations which add materially to the usefulness of a book of this kind, which is presumably intended to be at the worker's side in the laboratory. The plan adopted by the author is systematic and clear. In dealing with the chemical analyses of albuminoid ammonia, for instance, he first describes the process in a series of pithy sentences, to which he appends an "explanation," giving the *rationale* of the proceeding. Short notes are added dealing with points of importance. In most cases examples are given of problems that have been actually worked out in the laboratory, so that the student is able to follow the practical application of his knowledge. In reviewing this book one recognises the great development that public health has experienced during recent years. While it is most essential that earnest scientific workers such as Dr. Pakes should undertake high standard researches, it is evident that they are somewhat outside the field of labour of the average medical officer of health. All who have to encounter high standard examinations, or who wish to have a trustworthy book at hand, either to guide their work in the laboratory or to use as a book of reference, may with confidence be advised to buy forthwith Dr. Pakes' excellent volume.

#### BARR'S DISEASES OF THE EAR. (a)

THE fact that this excellent manual has already passed through two editions, and has now entered on its third, testifies to the worth of the book.

Dr. Barr lays down in the preface that his aim is "to present the main facts of otology in such a form as to meet the wants of medical students and practitioners." This end is quite achieved. Without giving too many details he has contrived to present a picture of otology which should be of great benefit to advanced students and practitioners of medicine.

The first six chapters are devoted to a general survey of the symptomatology, methods of treatment, &c., of ear diseases and those of the nose and throat which may be in relation to them. The remaining chapters describe more in detail the various subdivisions of aural disease. The chapter on the "Treatment of Intracranial and Vascular Complications of Purulent Disease of the Middle Ear" is especially deserving of praise, the illustrations being particularly good.

Special chapters are allotted to "Tinnitus Aurium" and "Deaf-mutism," in the latter of which the author states, with truth, that instruction by lip-reading to adults who have become totally deaf after childhood, and can make out but little of what is said to them is not sufficiently taken advantage of.

The method shown at page 18 as being Politzer's way of inflating the middle ear was not in general use in his Clinic in 1899. As the book is more particularly written for students and general practitioners the addition of a full page diagram of the normal membrana tympani might be of advantage.

A very useful appendix gives a list of formulæ recommended in the body of the book, and a full bibliography and index completes it.

### Medical News.

#### Dublin Sanitary Association.

At a meeting of the Dublin Sanitary Association, held on August 29th, the following resolution was unanimously adopted:—"That the Council of the Dublin Sanitary Association view with concern the great prevalence and fatality of diarrhoeal diseases among very young children in Dublin at present, and urge upon the parents of children resident in tenement houses the necessity for great care in the preparation of the food

intended for young children. The Council advise those parents to apply to the Public Health Office, Cork Hill, or at one of the city dispensaries for information as to the preparation and keeping of infants' food." The Council then adjourned.

#### Vital Statistics.

THE deaths registered in the week ending August 24th in 36 large towns of Great Britain and Ireland corresponded to an annual rate of 21.3 per 1,000 of their aggregate population, which is estimated at 11,463,026 persons in the middle of this year:—

Birkenhead 26, Birmingham 27, Blackburn 23, Bolton 20, Bradford 19, Brighton 19, Bristol 14, Burnley 17, Cardiff 14, Croydon 16, Derby 18, Dublin 24, Edinburgh 17, Glasgow 18, Gateshead 30, Halifax 17, Huddersfield 14, Hull 27, Leeds 24, Leicester 24, Liverpool 22, London 19, Manchester 26, Newcastle-on-Tyne 28, Norwich 21, Nottingham 23, Oldham 26, Plymouth 18, Portsmouth 21, Preston 21, Salford 27, Sheffield 25, Sunderland 29, Swansea 27, West Ham 22, Wolverhampton 21. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1.9 in Birkenhead, and 2.5 in West Ham; from scarlet fever 1.1 in Wolverhampton and 1.2 in Blackburn; from whooping-cough, 1.7 in Swansea; and from diarrhoeal diseases, 8.7 in Nottingham, 8.8 in Birmingham, 9.3 in Sheffield, 9.7 in Newcastle-on-Tyne, 10.1 in Salford, 10.4 in Manchester, 10.8 in Hull, 11.0 in Sunderland, and 14.6 in Gateshead. In none of the large towns did the death-rate from "fever" reach 1.0 per 1,000. The 58 deaths from diphtheria included 27 in London, 6 in Leicester, and 4 in Salford. No death from small-pox was registered in any part of the United Kingdom.

#### The Mortality in Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 51, Bombay 50, Madras 47, Paris 15, Brussels 14, Amsterdam 14, Copenhagen 25, Stockholm 18, Christiania 22, St. Petersburg 23, Moscow 23, Berlin 24, Hamburg 25, Breslau 36, Munich 20, Vienna 17, Prague 21, Buda-Pesth 16, Rome 20, Venice 20, Philadelphia 19.

#### The Chemists' and Druggists' Exhibition.

FOR the last seven years an annual Exhibition of Manufacturing Chemists and Druggists has been organised by the proprietors of our contemporary, the *British and Colonial Druggist*, that for the present year being held at the London Opera House during last week, and, judging by the number of exhibitors, it is evidently appreciated by a large section of the wholesale trade. Although exhibitions as a whole have been considerably overdone, and one is moreover very much like another, a good deal may be said in favour of a gathering of this nature, whereat manufacturers and importers bring their goods together under one roof and invite the retail chemists to come and inspect; the two branches are thus brought into personal contact, one might hope with mutual advantage. Few of the large houses were, however, represented on the present occasion, and one missed such well-known firms as Allen and Hurbury's, Burroughs and Wellcome, Martindale's, Southall's, Savory and Moore, Squire's, etc. The limited capacity of the building may, however, be in some measure accountable for this apparent want of interest. American houses were fully represented, Messrs. Parke Davis, the Merrell Chemical Co., Messrs. Warner and Co., Messrs. Stiles and Son, and the Abbey Effervescent Salt Co., &c., having large shows. Sponges, perfumery, soaps, and disinfectants were strongly in evidence, whilst cure-alls and pick-me-ups were to be had for the asking. Of the more serious British exhibits those of Messrs. Newbery and Sons, Thos. Christy and Co., Price's Patent Candle Co., Vinolia, Limited, Messrs. St. Dalmas and Co., Messrs. Wyleys of Coventry, the Somatose Co., the Sanitas Co., Bovril and Virol, Limited, and Messrs. Ingram and Royle may be mentioned as excellent representatives of home products, whilst the lighter portion of the programme was filled in by an up-to-date ladies' orchestra.

(a) "Manual of Diseases of the Ear, including those of the Nose and Throat in relation to the Ear, for the Use of Students and Practitioners of Medicine." By Thomas Barr, M.D. Third Edition revised, partially rewritten. Glasgow: James Maclehose and Sons. 1901. Pp. xxiii. and 429. Illustrations 236.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature* or *initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

### SUGGESTED COLLECTIONS FOR MEDICAL BENEVOLENT FUNDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On or about St. Luke's Day the members of the Guild of St. Luke hold their annual meeting, and have an anniversary service at St. Paul's Cathedral. I beg to suggest that a similar service be held in every town in the kingdom on that day or the following Sunday, and that a collection be taken at each, of which one-fifth be given to the British Medical Benevolent Fund, one-fifth to the R.M.B. College, Epsom, one-fifth to the Society for the Relief of Widows and Orphans of Medical Men, one-fifth to the Lancashire Relief Fund, and one-fifth to church expenses. &c. These most deserving charities would benefit greatly by these collections. St. Luke's Day, Oct. 18th, will this year fall on a Friday.

I am, Sir, yours truly,  
HORACE E. HAYNES.

**OUR PARIS CORRESPONDENT.**—Translation of the Clinical Lecture on "Vomiting in Pregnancy" was delayed in post, but has now come to hand.

**DR. HY O'HARA** (Melbourne).—Your interesting case of "Total Gastrectomy for Carcinoma of Stomach" has been received, and will appear in an early number.

**DR. W. W.**—It is hardly worth while calling attention to the matter unless correspondence should result. The explanation is obvious, we imagine.

**PATERFAMILIAS** The Scotch and Irish schools open somewhat later than those in England. You will find fees and relative cost of curriculum in our "Educational Number," to be published next week.

### PROF. ROBIN ON THE TREATMENT OF CANCER OF THE STOMACH.

A CORRESPONDENT having read the "Paris Clinical Lecture" on this subject in our issue of August 21st, and having much interest therein, wrote us that it was of extreme importance, but that there appeared to be a little discrepancy in the dosage. We thereupon referred the letter to our Paris correspondent who furnished the lecture, and append his reply, as it may be of interest to other readers also. He says:—

"There were evidently some slight errors, which may have been my fault in rapid translation or that of the printer. In any case, I proceed to correct them as follows, giving the exact copy of Prof. Robin's formulae:—

Persulfate de soude ... 1 gramme.  
Eau ... 150  
Une c. à café avant les deux principaux repas.  
Méla vanadate de soude ... 0'03 centigr.  
Eau ... 150  
Une c. à café avant les deux principaux repas.

Your correspondent can convert these figures himself, remembering that

One centigramme equals 0.15432 grains.  
One gramme equals 15.432 grains.  
One ounce equals 28.3495 grammes.

I am always very particular about formulae, but it would be invidious to state fractions of ounces and grains. For instance, one grain ought to represent five centigrammes, while in reality it is seven centigrammes. Ounces, drachms, scruples, &c., constitute an anachronism to-day. The French metric system ought to be adopted everywhere. It is much easier."

### Appointments.

**EMINSON, L.**, L.F.P.S.Glasg., L.S.A., District Medical Officer of Cosford Union.  
**FORBES, N. HAY**, F.R.S.Edin., J.P., Honorary Consulting Surgeon to the Black Rock Convalescent Hospital, and Consulting Surgeon to the Rother Valley Railway Company.  
**LAING, C. F.**, M.B., C.M.Glasg., Medical Superintendent to the Somerset and Bath Asylum.  
**MILES, H. P.**, M.R.C.S. L.R.C.P.Lond., District Medical Officer of Kingsbridge Union.

### Vacancies.

**British Medical Temperance Association.**—Assistant Secretary. Must be a qualified practitioner, a total abstainer, and able to speak in public. Salary £150 per annum, with lecture fees and board and residence. Applications to the hon. sec., Dr. Ridge, Carlton House, Enfield. (See advt.)

**Birmingham and Midland Ear and Throat Hospital**, 109, Edmund Street, Birmingham.—House Surgeon. Salary at rate of £40 per annum for first six months, and if re-appointed, at rate of £60 per annum, with board, lodging, and washing.  
**Cheeshire County Asylum**, Parkside, Macclesfield.—Junior Assistant Medical Officer, unmarried. Salary £130, rising to £150 per annum, with board, apartments, washing, and attendance.  
**City of Nottingham Workhouse Infirmary.**—Assistant Medical Officer. Salary £160 per annum, with furnished rooms.  
**Cornwall County Asylum**, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, furnished apartments, &c.  
**County Asylum**, Lancaster.—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, with apartments, board, washing, and attendance.  
**East Riding of Yorkshire.**—County Medical Officer of Health. Salary at rate of £400 per annum, rising to £500 per annum, with allowances. (See advt.)  
**Glamorgan County Asylum**, Bridgend.—Assistant Medical Officer, unmarried. Salary £175, with board, lodging, attendance, and laundry.  
**Glasgow University.**—Additional Examinership in Medicine and Science. Annual emolument £30. Duties to commence in January, 1902. (See advt.)  
**Great Northern Central Hospital**, London.—Vacancies for House Physician. Salary £60 per annum; Junior House Physician, Salary £30. Board, residence, and washing provided in each case. Also Junior House Surgeon, Salary £30, with board, residence, and washing; and a non-resident Assistant House Surgeon, with Salary at rate of £30 per annum, and partial board. Full particulars of these vacancies will be found in our advertisement columns.  
**Kaar-el-Ainy Hospital and School of Medicine**, Cairo, Egypt.—Physician to the Hospital and Professor of Clinical Medicine at the School. Salary £E320 per annum and private practice allowed.  
**Manchester Children's Hospital.**—Junior Resident Medical Officer, unmarried, for six months, and eligible for election as Senior for another six months. Salary at rate of £80 a year when Junior, and £100 a year as Senior, with board and lodging.  
**North Wales Counties Lunatic Asylum**, Denbigh.—Second Assistant Medical Officer. Salary £120 per annum, rising to £160, with board, residence, and washing.  
**Owens College**, Manchester. Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.  
**Royal South Hants and Southampton Hospital.**—Junior House Surgeon for first six months. Salary at rate of £50 per annum, with rooms board, and washing.  
**Salford Royal Hospital.**—House Surgeon, salary, £100 per annum; House Physician, salary £80 per annum; and Junior House Surgeon, salary £70 per annum, with board and residence in each case.  
**Swansea Union Workhouse.**—Assistant Medical Officer. Salary £200 per annum.

### Births.

**BOXALL.**—On August 26th, at Portland Place, London, W., the wife of Robert Boxall, M.D.Cantab., of a daughter.  
**GILLESPIE.**—On August 31st, at 12, Walker Street, Edinburgh, the wife of A. Lockhart Gillespie, M.D., F.R.C.P.E., of a daughter.  
**JOSCELYNE.**—On August 26th, at The Homestead, Southwick, Sussex, the wife of E. W. Joscelyne, M.B.Durh., of a son.  
**MATTHEWS.**—On August 27th at Holly Lodge, Crawley, the wife of Sidney Matthews, M.R.C.S.Eng., L.R.C.P.Lond., of a son.  
**WIELD.**—On August 29th, at Wickham Terrace, Brisbane Queensland, the wife of David Wield, M.D., of a daughter. (By cable.)

### Marriages.

**GUTCH—METCALFE.**—On August 27th, at St. Michael's Church, Sutton, Wansford, Northants, John Gutch M.D.Cantab., of Ipswich, eldest son of the late John James Gutch, of Holgate Lodge, York, to Dorothy Emily, second daughter of the late Frank Metcalfe, of Mote House, Wisbech, and of Mrs. A. Metcalfe, Manor House, Sutton.  
**NEWSOME—GIBBS.**—On August 22nd, at St. Stephen's Church, Redditch, Herbert Newsome, M.B., F.R.S.Durh., late R.N., to Christine Margarite, youngest daughter of William Gibbs, Esq., Crossies, Redditch.  
**SULLIVAN—DUNCAN.**—On August 27th, at St. Katharine's Church, Bow, P. Sullivan, L.R.C.P., L.R.C.S., &c., of Campbell Road, Bow, to Janet Blanthorne, younger daughter of Captain Robert Duncan, of the R.E.M.S. *Kinfauns Castle*, and of Forest Gate.

### Deaths.

**BUCKLEY.**—On August 26th, at Linden Gardens, Kensington, Henry Child Buckley, M.B., M.S.Aberd., J.P., aged 57 years.  
**COLTART.**—On August 28th, at the Grange, Ruthin, Wales, Charles H. R. Coltart, eldest son of William Coltart, L.R.C.P., M.R.C.S., of Epsom, aged 30 years.  
**KELLY.**—Suddenly, on August 18th, Adam Lawson Kelly, M.D., F.F.P.S.Glasg., aged 66 years, of 26, Blythwood-square, Glasgow.  
**LAWRENCE.**—On August 30th, suddenly, whilst on a holiday in Devonshire, Alfred E. Austin Lawrence, M.D.Aberd., M.D.C.M., of Clifton, Professor of Midwifery and Diseases of Women in University College, Bristol.  
**LIVETT.**—On August 21st (the 87th anniversary of his birth), at Wells, Somerset, Henry William Livett, M.D., L.R.C.P.Edin.  
**TUKE.**—On August 26th, at 39, Drayton Gardens, South Kensington, very suddenly, John Henry Tuke, M.R.C.S., L.S.A., formerly of Week St. Mary, Stratton, Cornwall.

"SALUS POPULI SUPREMA LEX."

VOL. CXXIII.

WEDNESDAY, SEPTEMBER 11, 1901.

No. 11.

## EDUCATIONAL NUMBER, 1901—1902.

### INTRODUCTORY REMARKS.

In the present number will be found a synopsis of the information likely to be useful to those who intend to enter upon the study of medicine, and to serve as a guide to parents and guardians upon whom devolves the responsibility of selecting, not only a particular school, but also a plan of campaign in general. The decision must necessarily be largely influenced by the student's means by his aptitude for study, and by individual circumstances, in so far as they bear on his future career. It is not always possible to determine at that early stage what particular line of practice is to be aimed at. The great thing to compass is a thorough knowledge of the subjects which form the basis of medical education, leaving it to circumstances to settle the question whether general practice or some more specialised department is to be followed.

One point, however, must be settled at the very outset, under penalty of losing much valuable time, viz., whether the student is to content himself with an ordinary license to practise medicine or whether he will aim at university graduation. As years pass by students display more marked appreciation of the advantages which the possession of a university degree unquestionably offers, but there will always remain a large proportion who are constrained to be satisfied with a mere license by reason of a comparatively low standard of preliminary education or because, for pecuniary reasons, they desire to obtain the right to practise at the earliest possible moment. Having made up his mind which course he will pursue the next step is

#### THE CHOICE OF A SCHOOL.

The difference in the amount of the fees exacted by the various medical schools is hardly such as to make the choice of a school a matter to be decided merely by reference thereto. In many instances the choice will be determined by heredity, so to speak, that is to say, by the fact that the student's father or friends has or have been previously associated with a particular school. A more judicious choice may be made by considering the neo-student's intellectual calibre. In a large school he will be subjected to more severe competition, but, as a set-off to this, the prizes are more valuable, and the experience gained in certain respects more comprehensive. Moreover, he is brought into contact with a larger number of those who have attained eminence in their profession, and he makes a larger number of acquaintances as fellow students. In the smaller schools, on the other hand, he comes into far more intimate contact with his teachers, who consequently take a keener interest in his subsequent career. The chances

of obtaining resident appointments at the close of his student career are greater than in the larger schools where the competition for such posts is very sharp, and as dresser and clerk his opportunities for obtaining practical experience are often greater than in the large schools where the number of students is out of proportion to the number of beds. We need not allude here to the possibility of gaining an entrance scholarship, of which there are usually several at most medical schools, because the examinations have already been held.

#### THE CHOICE OF A QUALIFICATION.

While all qualifications nominally confer equal rights in regard to medical practice the selection is fraught with consequences of exceeding gravity. The public, no doubt with some reason, accord special importance to a medical degree as compared with a mere license to practise, so that it is desirable, within the limits of the possible, for the student to aim at obtaining a degree. Apart from this, there are certain qualifications which confer special privileges; for instance, no one can hold an appointment in any of the larger hospitals without being a Member or Fellow of the Royal College of Physicians or Fellow of the Royal College of Surgeons. This is a relic of bygone times, but it still holds good, and has to be borne in mind. The Membership of the Royal College of Physicians is a trying ordeal, not so much by reason of the high standard of knowledge required as of its uncertainty. It is well not to enter the lists until some years have elapsed since qualification. The Fellowship of the College is conferred by a kind of "selection by election," and the selection is made on grounds often quite foreign to professional attainments. The Fellowship of the Royal College of Surgeons, on the other hand, is obtained almost exclusively by examination. All that is required is a high standard of knowledge, both theoretical and practical. Although the possession of the licence of the Apothecaries' Society as a single qualification is looked at askance, even in general practice, it is often useful in order to qualify for a resident appointment pending the student's subsequently obtaining a degree. It must not be forgotten, moreover, that the nature of the qualification is an all-powerful factor in competing for public appointments, to obtain which will be the aim of so many students when prepared to launch forth.

Apart from the resident appointments in the general hospitals there are a large number of appointments available in special hospitals, where experience of a useful kind is to be obtained. These, it is true, lack the social charms of residence in large hospitals where the resident officers are numerous, but, on the other hand

they present advantages which the others do not offer and which cannot fail to favourably influence the practitioner's subsequent career. We do not advise these appointments being taken immediately after qualification with the object of paving the way to taking up a speciality. It is an old maxim that no man should become a specialist until he has had some years experience in general practice.

Consultant rank is only to be obtained by long service and tedious waiting. Apart from the special qualifications which the consultant must possess he has to climb the ladder of promotion in competition with a crowd of rivals, and it will be many years before he can reach the point at which he may hope to reap the fruits of his labours.

#### THE PUBLIC HEALTH SERVICE.

Under existing circumstances the public health service offers plenty of scope for intelligence, tact, and activity. Those only are eligible for any important post in the service who are provided with a diploma in State Medicine. This diploma cannot be obtained for at least two years after qualification, and it entails a somewhat arduous course of study, both theoretical and practical. These appointments, which are determined by election, are under the disadvantage of a certain insecurity of tenure in that they are made for a term of years, usually three. To men possessed of the requisite energy and scientific spirit the position of medical officer of health offers exceptional opportunities for carrying on scientific investigations, and success in this department may pave the way to an appointment under the Local Government Board, though this department of the service is by no means exclusively recruited from among medical officers of health. In addition to a fairly liberal salary these appointments carry the right to a pension after a certain period of service. We would point out the advantage to all students of obtaining the special diploma in State Medicine. Not only is the knowledge thus acquired of extreme utility in practice, but it may prove of inestimable value in later life under circumstances which cannot always be foreseen. Once engaged in general practice the difficulties in the way of obtaining it are well nigh insuperable.

#### THE SERVICES.

Under the head of "The Services" we include the Army, the Navy, the Indian and the Colonial Services. For the time being these outlets fail to attract their quota of the newly-qualified, owing to circumstances into which we need not enter. No better evidence of this is needed than the fact that at the last competitive examination not a single candidate entered for either the Army or Navy. Students therefore will do well to hesitate before they decide on joining one or either of them. The quasi-impossibility of filling the *cadres* will doubtless induce the Government to reconsider the terms and conditions under which candidates are invited to compete, and then the Services may once again prove an attraction to many young medical men. The nomad existence which these posts entail is of itself a great drawback and to some extent the routine work tends to unfit fit men for general practice. These, however, are probably not the reasons which tend to create a prejudice against the Services which indeed is based rather on the unsatisfactory nature of the position *per se*.

#### THE COURSE OF STUDY.

There is so much work to be got through in the present-day curriculum that the student will find it absolutely necessary to be methodical in his studies. He will have to plan out his day with attendance at lectures, practical work at dissection, laboratories, or in wards, and so many hours reading. At the same time he will find it well to keep up regular exercise by walking, cycling, cricket, tennis, rowing, football, and other athletic games. Those who enter in the Winter Session will devote most of their attention to anatomy and physiology, and it will be found greatly to their interest to have got rid of the preliminary scientific work—chemistry, physics, and biology—before entering the medical school. Anatomy and physiology form two of the most essential bases of study, and on the thoroughness with which they are handled will depend much of the success of the student's subsequent career. The importance of practical work in the dissecting-room can hardly be over-rated, and we are fain to endorse the protest which has been raised against the modern tendency to scamp actual dissection in favour of book work with text-books and atlases. The study of anatomy affords a valuable training to the mind, as well as furnishing information that is of daily use in the practice of after life, to say nothing of the manual skill and dexterity that is acquired by careful dissection.

#### THE WARDS.

After the student has passed the examination in anatomy and physiology at the end of the second academical year his transfer to the wards of the hospital will come as a pleasant change. That will be his first entrance into the arena where medical science is ever carrying on the war against disease and death. In the wards it will be his privilege step by step to unravel the tangled threads of the history of each patient, and from the careful collection and examination of facts to arrive at the systematic conclusion known as diagnosis. This period of a student's life is big with possibilities both for good and for evil. It is then that he will lay the foundation of his future grasp of the principles that lie at the root of his profession, a competent knowledge of which can be gained only by careful and conscientious attention to

#### CLINICAL WORK.

This may be called the corner-stone of medical education. In each patient brought under his notice the student has the means of acquiring practical knowledge, but the value of the opportunity depends absolutely on his ability and his willingness to observe. It may be said that all science is observation, and it is certainly true that the chief end and aim of all clinical training is to teach the student how to observe. The difference between a trustworthy and an untrustworthy practitioner lies mainly in the fact that the former has learnt how to test his observations in such a way as to arrive at the truth. This faculty is one that can be acquired by systematic training, which in its turn mainly consists in taking an accurate and faithful record of clinical cases. The habit of careful observation is one which becomes a second nature to the individual who has once become its possessor.

#### THE POST-MORTEM ROOM.

We would strongly advise every student to spend as much time as possible during the last three years of his

studies in the post-mortem room. The post-mortem room is the natural complement of the clinical wards, it is often only in this room that the clinical problem is unravelled, it is there that the student can see for himself the physical results of the processes of disease which he has been watching at the bedside. He learns too, as he can never learn in the dissecting room, to recognise the post-mortem appearances of the various viscera, and to distinguish between changes due to decomposition and those caused by the ravages of disease. The lack of this familiarity has over and over again led to errors of the gravest kind, errors which have had for effect to jeopardise the administration of justice and perchance to place innocent persons in the most serious predicaments.

#### POST-GRADUATE INSTRUCTION.

The earnest student will soon recognise that his five years' training do little more than to fit him to carry on the acquisition of knowledge under favourable conditions. Woe to the man who conceives that he has done all that is required of him when he has obtained the right to practise! The need for further opportunity for study, so generally felt of late years, has found expression in the provision of multiple facilities for post-graduate study. At many of the larger hospitals post-graduate classes have been instituted for the benefit of practitioners who are desirous of remedying the lapsus of medical education, and in London an admirably organised institution—the Polyclinic—is now in full working order, and renders immense service to those who are fortunate enough to be able to avail themselves of its advantages. We would urge upon practitioners the importance of belonging to some local medical society which has the advantage of bringing them into personal contact with their fellow practitioners, and of generalising the knowledge which each individual practitioner has gleaned.

#### THE PRACTICE OF MEDICINE.

To those possessed of the proper spirit and who are equipped with the requisite knowledge, the practice of medicine is not only the means of gaining a livelihood, it is also a congenial and interesting occupation. It brings a man into contact with all classes of society on terms of quasi-equality, and affords unlimited scope for the cultivation of the noblest qualities of humanity. The duty of the practitioner is two-fold—he has a duty to the public and a duty to his profession. His attitude towards his fellow practitioners should be characterised by the courtesousness due to a labourer in the same field, and he should studiously avoid all possible sources of friction. It is an immense advantage to be personally acquainted with one's fellow practitioners in the district, for, as it has been aptly observed, every man is an enemy until you know him. The code of medical ethics in reality does not go further than to enjoin our acting towards others as we would have them act towards ourselves. Any infringement of this code recoils upon the delinquent who thereby forfeits the esteem of his fellows, and, though he may not believe it, the respect of the public. Lastly, all should remember that they are members of an honourable profession, whose traditions should command respect.

#### FOREIGN DIPLOMAS—PRACTICE ABROAD.

The principle of reciprocity of medical practice has

at last been formally recognised by the Privy Council directing the admission of medical graduates of Italian universities to practise in this country subject to recognition by the General Medical Council. In virtue of this agreement, certain, or rather uncertain, facilities are conceded to British practitioners to practise medicine in Italy. The exact terms have not as yet been made public, but in all probability it would suffice to make application to the proper Government department to obtain permission to practise in that country, though as matters stand that right only extends to attendance on the fellow countrymen of the practitioner.

In France the difficulties of obtaining the right to practise have been considerably enhanced of late years; indeed, measures are contemplated which would have for effect to exclude foreign students from pursuing their studies in Paris altogether on the ground that the faculties are already overcrowded. A modified degree is conferred upon foreign students on certain conditions, but this does not carry the right to practise, so that it possesses a merely decorative value. To obtain the right to practise medicine within the territory of the French Republic the student must pass the matriculation examination (baccalauréat), and go over exactly the same ground as the native student, and no exemption from any part of the course of study or examinations is now accorded. The curriculum in France nominally extends over four years, but in practice it extends to five and even six years. The details can be obtained on application to the Dean of the particular university selected.

#### LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lectures, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

**ST. BARTHOLOMEW'S HOSPITAL.**—This hospital has 750 beds, and for many years past the school attached has had a larger number of entries than any other medical school in London. Collegiate residence is here permissible, subject to the ordinary rules. The recreation ground for the use of students is at Winchmore Hill.

**Appointments.**—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Two assistant electricians are appointed every six months, and in-patient dressers, in-patient clinical clerks, clerks and dressers to the assistant physicians, and to the physicians and surgeons in charge of special departments are appointed every three months without fee.

**Scholarships, &c.**—There are four open scholarships in science, £75, £75, £150, £50, tenable for one year, and a Jeaffreson exhibition, value £20; four junior scholarships of £80, £25, £20 and £10, respectively; Treasurers'

prize for practical anatomy; Foster prize in practical anatomy; senior scholarships, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Blakenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10 and Matthews Duncan medal and prize, value about £20; the Treasurer's Research Studentship, of the value of £100, is given annually, the elected student being required to engage in original research in pathology.

*Fees.*—Fees for perpetual attendance on lectures and hospital practice, 160 guineas, payable in the following instalments:—First year, 40 guineas; second year, 40 guineas; third year, 40 guineas; fourth year, 40 guineas; or a single payment of 150 guineas. Fee for general subjects for students of dental surgery: First winter, 31½ guineas; first summer, 31½ guineas, or a single payment of 63 guineas. Fee to University students, 80 guineas; fee for laboratory instruction for D.P.H., 20 guineas; composition fee to University of London students for one year's instruction for the Preliminary Scientific Examination, 20 guineas. Composition fee to University of London students who have passed the preliminary scientific examination, 150 guineas.

The Warden, Dr. James Calvert, will furnish further details on application.

**CHARING CROSS HOSPITAL.**—The school attached to this hospital is situated in central London, and contains new physiological, pathological, and bacteriological laboratories, *materia medica* museum, an anatomical theatre, enlarged dissecting-room, and chemical theatre. The hospital, which is now being enlarged, contains 180 beds, making, with the 30 beds at the adjoining Royal Westminster Ophthalmic Hospital (to the practice of which general students are admitted free) a total of 210 beds available for clinical study.

Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, mental disorders, the throat, the nose and ear, and in the orthopedic, Röntgen, and electrical departments.

*Scholarships, Medals, &c.*—Five entrance scholarships, the Livingstone scholarship, 60 guineas, and 55 guineas; Huxley scholarship, 40 guineas and 30 guineas. Three (100 guineas, 60 guineas, and 40 guineas) are open to all general students, one (55 guineas) is reserved for the sons of medical men, and one (30 guineas) is open to dental students only. All are awarded annually. Two Universities scholarships, value 60 guineas each, are open to students from the University of Oxford who have passed the 1st M.B., to students of the University of Cambridge who have passed the 2nd M.B., and to students of the University of London who have passed the intermediate examination in medicine. Candidates must give notice to the librarian of their intention to compete on or before September 21st, 1901. The Golding Prize of £10 is open to students at the end of their first winter session. The Huxley Medal, with prize of £10, is open to students at the end of their second winter session. The Pereira Prize of £5 is open to all general students. The Llewellyn Prize of £25 is awarded annually at the end of the curriculum. The Governors' Clinical Gold Medal is also open to students at the end of their curriculum, and a silver medal or its equivalent in books, is awarded to the most distinguished student in each class.

*Appointments.*—The curator and pathologist is appointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each, with luncheon in the hospital; obstetric registrar, six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks, dressers, and surgical ward clerks are appointed in all the general and special departments of the hospital.

*Fees.*—For the curriculum of study required by the various examining bodies and hospital practice, 110 guineas in one sum, or 121 guineas in five instalments.

The composition fee for sons of registered medical practitioners is 110 guineas, and the fee by instalments, 121 guineas. For dental students, 54 guineas in one sum, or 60 guineas payable in two instalments.

**ST. GEORGE'S HOSPITAL.**—This hospital is situated in a favoured position in the West End, facing Hyde Park. It contains 350 beds, and special wards for ophthalmic cases and diseases of women.

*Appointments.*—Four house physicians and four house surgeons, entitled to reside and board in the hospital free of expense; two assistant house physicians, two assistant house surgeons, four assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, and hold all the offices in succession during a period of two years, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £100 and board and residence in the hospital; pathological curator with a salary of £100; assistant curator with a salary of £50; two medical registrars, with salaries of £50 and £30 per annum; a surgical registrar with a salary of £50 per annum; an administrator of anaesthetics with a salary of £50 and two with salaries of £30 per annum; a surgery officer with a salary of £100 a year; three demonstrators of anatomy with a salary of £50 each; and assistant demonstrators. All offices are open to candidates without additional fee.

*Exhibitions, &c.*—The Brown exhibitions, one of £100 per annum, tenable for two years, and open to perpetual pupils possessing a registrable diploma; and one of £40 per annum, tenable for three years and open to students in their third year. The Braekenburg prizes of the value of £40 each, one each in medicine and surgery. The Webb prize in bacteriology, value £30. The Clarke good conduct and clinical work prize in surgery, the Thompson medal, the Brodie clinical prize in surgery, the Acland clinical prize, the Johnson prize in anatomy, the Pollock clinical prize in physiology, the Treasurer's prize for clinical reports, and four general proficiency prizes of ten guineas each.

*Scholarships.*—One in arts of £150 for sons of medical men who have entered the school during the current year. Two in arts of £50, open to commencing students, and a further scholarship in arts of £50 to sons of officers of His Majesty's service, who have met their death by serving in the South African campaign. Examination, September 24th. Two of £35 in anatomy and physiology, open to students who have signed up for or passed the first M.B. Oxford or second M.B. Cambridge. One of similar value for students of Provincial University colleges of similar standing. Examination, September 24th.

*Fees.*—Composition fee for perpetual pupils, £150, or £160 in the following instalments: First year £50, second year £50, third year £40, fourth year £20. The fee for general subjects in dental surgery is £55, payable in two instalments: first year £30, second year £25. Only perpetual pupils can hold house office or compete for the Brown exhibitions.

**GUY'S HOSPITAL.**—This hospital is situated on the Surrey side of London Bridge, and contains 554 beds with special wards for ophthalmic and obstetric cases. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is now a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England, the facilities thus afforded of completing the whole course of dental study within the walls of one hospital will be appreciated by those intending to practise dentistry.

*Re-opened Ward.*—One of the wards which have for many years been closed for want of funds was re-opened in October, 1898, as a special ward for diseases of women, eight beds being set apart for difficult cases of labour. An obstetric registrar and tutor and an ophthalmic registrar and tutor have been appointed to augment the teaching in the special departments.

*Appointments.*—Eight house surgeons, eight house physicians, eight assistant house physicians, twenty-four

assistant house surgeons, eight obstetric residents, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

**Scholarships.**—Open scholarships of £100 or £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £80 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. Six scholarships, varying in value from £13 to £25 each, for general proficiency in medical study, open to students of different years. The Treasurer's gold medal in medicine; the Treasurer's gold medal in surgery; the Sands Cox scholarship of £15 per annum for three years for physiology; the Michael Harris prize of £10 for anatomy; Beaneys prize in pathology, 30 guineas; the Beaneys scholarship in materia medica, 30 guineas; the Golding-Bird gold medal and scholarship (£20) for sanitary science; and the Gull Research scholarship of £150 per annum. The Physical Society awards two prizes, each of £5, to the authors of the best essays on selected subjects, prizes of £10 and £5 for the best papers read before the Society, and a prize of £5 to the member who has most distinguished himself in the debates of the session.

**New School Buildings.**—A considerable addition to the school buildings was opened in 1897, comprising a series of class-rooms, laboratories, and a lecture theatre for the teaching of physiology.

**Fees.**—For the entire course of lectures and hospital practice, 150 guineas, if paid in one sum on entrance; or payment may be made by four instalments of 40 guineas each, payable at the beginning of the first, second, third, and fourth years respectively.

**KING'S COLLEGE HOSPITAL.**—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House, and is close to the hospital, in which there are 220 beds available for clinical teaching; ophthalmic, ear, throat, skin, and dental departments, are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been recently refloored and the electric light installed throughout.

**Scholarships.**—£800 are awarded annually in scholarships and prizes. At entrance two science exhibitions of £60 and £40 value are open to all candidates under the age of nineteen; two scholarships of the value of £75 each (subjects literary) and two exhibitions of the value of £60 and £40 each (subjects scientific) are open to students commencing their curriculum. Two scholarships, value seventy and sixty guineas, are open to students of a British University who come up to London to complete their curriculum; two junior scholarships of £20 each for first year students, one of £30 for second year students, one of £50 for third year students in residence, and one of £40 for fourth year students. In addition students may compete for the Daniell scholarship, value £40; the Warnford prizes, value £40; the Rabbeth scholarship, value £20; the Carter, Todd, Jelf, Tanner, Leathes prizes, and all class and clinical prizes.

**Appointments.**—Medical and surgical Sambrooke registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, viz., senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

**Residence of Students.**—There are chambers allowing a limited number of students the opportunity of residing at the College.

**University of London.**—Special courses of lectures and practical instruction in the chemical, physical, and physiological laboratories have been arranged for students preparing for preliminary scientific, and

intermediate science examinations of the University of London.

**F.R.C.S. Examinations.**—Special classes are arranged for both the primary and final F.R.C.S. examinations. Further particulars can be obtained from the Dean.

**LONDON HOSPITAL.**—This hospital is the largest in the United Kingdom, containing as it does, 800 beds. It has, moreover, wards and a teaching staff for almost every special department in the domain of medicine: the scholarships and prizes are many and valuable, and both school and staff are deservedly popular with students.

**Scholarships and Prizes.**—At Entrance.—Prize scholarship in science, £120; Prize scholarship in anatomy and physiology, £60; entrance scholarships in science, £80 and £35; Epsom scholarship, £126; Buxton scholarships in arts, £30 and £20. After Entrance.—Anatomy and biology scholarship, £20; anatomy and physiology scholarship, £25; Letheby prize, senior, £20; Letheby prize, junior, £10; scholarship in clinical medicine, £20; scholarship in clinical surgery, £20; scholarship in clinical obstetrics, £20; Duckworth Nelson Prize, £10; Hutchinson prize, £35; Sutton prize, £20; Sir Andrew Clark prize, £26; Anderson prizes, £9; Out-patient dressers' prizes, £60; practical anatomy prizes, £10.

**Appointments.**—The "House" appointments, which are more numerous than at any other hospital in the Kingdom, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in a few instances with a small salary also.

The additional buildings for the department of public health, for the biological, chemical, and physical laboratories, materia medica museum, &c., and the new bacteriological department with general laboratory, research laboratories, class rooms for D.P.H. work, sterilising room, animal room, &c., are now open. For all these departments, special teachers have already been appointed who are devoting their entire time to the particular subjects that they have undertaken. In addition to these alterations and additions, arrangements have been made in the hospital for additional clinical teaching.

**Fees.**—Perpetual fee for lectures, demonstrations, and Hospital Practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the 1st, 2nd, and 3rd years respectively, 130 guineas; or if in one payment, 120 guineas. A reduction of 8 guineas for chemistry and physics, and 5 guineas for elementary diology is made from the above fees, in the case of students who have passed in these subjects at the First-Conjoint Examination before entering the College. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school elsewhere), 65 guineas. (This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London.) Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

**Notes.**—A reduction of 15 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses of lectures for hospital practice.

Accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Dinners and luncheons are provided in the Students' Club, which, with the reading and smoking rooms, now form part of the college buildings. The "London Hospitals' Club Union" has a field for cricket, football, &c., with an excellent pavilion, at Lower Edmonton. The clubs and societies are open to all the students, and are warmly encouraged by the staff. The new club rooms, gardens, and forecourt are now open. Full particulars of the Warden, Dr. Munro Scott.

**ST. MARY'S HOSPITAL.**—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 281 beds. Fresh laboratories, fitted with electric light and all modern improvements, for the study of pathology and

bacteriology, have recently been added, and also a new physiological lecture-room. During the past year a special department of pathological chemistry has been instituted.

*The New Wing.*—The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, is about to be completed. This will add to the hospital 100 new beds, and will include an additional operating theatre, a new clinical laboratory, and an X-ray department.

*Appointments.*—All clinical appointments in the Hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anaesthetists are appointed in each year, and receive board and residence in the Hospital.

*Scholarships, &c.*—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. Two scholarships in natural science, each of the value of £78 15s., and one of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from the Universities of Oxford and Cambridge. The scholarships will be awarded by examination on September 24th and 25th.

*Fees.*—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, including membership of the Library, Medical Society, Students' Club, and all the athletic clubs, and the receipt of the hospital Gazette for five years, £140 paid in one sum on entering the school; or in instalments, £145

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

*Preliminary Scientific Course.*—Special classes, including lectures and laboratory work, are held throughout the year.

**MIDDLESEX HOSPITAL.**—This hospital, which is conveniently situated in the centre both of business and residential London, contains 340 beds. There are special departments for cancer, and for ophthalmic, throat, aurial, skin, dental, and children's diseases. Wards are also devoted to cases of uterine disease and of syphilis. The new school buildings are now in regular use. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

*Appointments.*—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

*Scholarships, &c.*—Two entrance scholarships of the value of £100 and £80 respectively. One entrance scholarship of the value of £60, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21 for students in their final year. Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery and obstetrics; the Lyell Gold Medal in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynecology; exhibitions of 10 guineas and 5 guineas for anatomy and physiology to second and first year's students respectively, as well as class prizes in all subjects.

*Fees.*—General fee for the entire course of hospital practice and lectures, 135 guineas if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas,

payable at the commencement of the first, second, and third years respectively. General fee for members of a University who have completed one year of medical study, 80 guineas if paid in one sum, or by instalments of 60 and 40 guineas. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students who have passed the preliminary science examination is 115 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

**ST. THOMAS'S HOSPITAL.**—This hospital, with its medical school attached is one of the schools of the University of London. It is situated on the southern embankment of the Thames, facing the Houses of Parliament, and contains 572 beds, of which about 512 are in use. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all the subjects of medical curriculum. There is a large library and reading room, and a very complete museum and gymnasium. A ground of more than nine acres in extent is provided at Chiswick for out-door sports.

A clinical laboratory has been recently built, in which all the more difficult methods of diagnosis, bacteriological, chemical, and microscopical, are carried on under the direction of a superintendent. The department for out-patients has been re-arranged, so that large numbers of students are enabled to follow closely the practice and teaching of the assistant staff. To this department there has been added a completely fitted operating room.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging. Two hospital registrars, at an annual salary of £100 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Four house physicians, two assistant house physicians, four house surgeons, four assistant house surgeons, two obstetric house physicians, two ophthalmic house surgeons, and eight clinical assistants in the special departments are appointed every three months. Clinical clerkships and dresserships to in- and out-patient departments are available to the number of more than 400 each year.

*Scholarships, Prizes, &c.*—Three entrance scholarships are offered for competition in September, viz., one of £150 and one of £80 in chemistry and physics, with either physiology, botany, or zoology at the option of candidates for first year's students; one of £50 open to University students who have passed in anatomy, physiology, materia medica, and pharmacy for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London medical school. Copies of the examination papers of last year may be obtained on application to the medical secretary. Applications must be sent in not later than September 17th, with certificate of birth and of preliminary examination, and with a notification as to the optional subject chosen. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology.

*Fees.*—The fees may be paid in one sum or by instalments. Entries may be made separately to lectures or to hospital practice. Special arrangements are made for students from the Universities and elsewhere entering in their second or subsequent years, also for dental students and for qualified practitioners.

Special classes for the Preliminary Scientific and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary F.R.C.S., are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners

and others who receive students into their houses. The prospectus of the school, containing full particulars as to fees, course of study advised, &c., and all necessary information, may be obtained on application to Mr. Bendle, the medical secretary.

**UNIVERSITY COLLEGE HOSPITAL.**—This hospital is situated in Gower Street, not far from Euston Railway terminus. The college where the classes are held faces the hospital, on the opposite side of the street. The number of beds available for teaching purposes is 210.

**Appointments.**—Eight house physicians, six house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants, are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

**Scholarships, &c.**—Entrance scholarships: One of the value of £120, and two of 55 guineas for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 76 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £110 a year, tenable for three years; Filiter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10., awarded for practical surgery, Dr. Fellow's clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, class medals, &c.; gold and silver medals, or other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £80 for chemistry, two years; and the Clothworkers' exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

**Fees.**—The following have been grouped to meet the requirements of the various examining boards:—1. For the medical examination required by the Examining Board in England and the Society of Apothecaries: 150 gs. if paid in one sum at the commencement of the course; 155 gs. if paid by instalments. 2. For those students who do not require to attend chemistry, pharmacy, and elementary biology at a medical school (under the regulations of the examining board in England) the fee is: 135 gs. if paid in one sum; 140 gs. if paid by instalments. 3. For the courses necessary for the Preliminary Scientific Examinations of the University of London, 25 gs. 4. For the course of instruction for the Intermediate Examination in Medicine of the University of London, 60 gs. paid in one sum. 5. For the course of instruction for the final M.B. examination of the University of London, 80 gs. if paid in one sum; 82 gs. if paid by instalments. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham. 6. Composition fee for dental students, for the courses required for the L.D.S., 65 gs. or exclusive of chemistry, practical chemistry, physics, and *materia medica*, 50 gs. The composition fees, 1, 2, 4, and 5, admit to attendance on systematic lectures and to hospital practice, where this is included in the fee, during five years.

**WESTMINSTER HOSPITAL.**—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

**Appointments.**—Medical and surgical registrars, each

£40 per annum; two house physicians, two house surgeons, two assistant house surgeons, and resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Fourth year's students are appointed to be clinical assistants in the various departments.

**Scholarships, &c.**—(a) Winter Session.—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry, and either Greek, French, or German. Oxford and Cambridge scholarships, £40 and £30, subject, anatomy and physiology. Natural science scholarship, £60, same as for Prel. Sci. of University of London. Natural science scholarship, £40, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (b) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship £60, arts scholarship, £40, Oxford and Cambridge scholarships £40 and £30, subjects same as in winter session. (c) Prizes.—Treasurer's, 10 guineas, for first year's men; Chadwick, 20 guineas for students of any year not exceeding fifth. To be competed for by unqualified men. Bird medal and prize, £14, for students who have completed fourth winter session. Sturges prize in clinical medicine £8, clinical surgery prize £5, to be competed for by unqualified men. And class prizes in the various subjects.

**Fees.**—In one payment of 110 guineas, or two payments of 60 guineas each, payable on entrance, and at the commencement of second year respectively, or by six payments distributed over six sessions of 25 guineas and 20 guineas alternately. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £27 10s.

**LONDON SCHOOL OF MEDICINE FOR WOMEN (ROYAL FREE HOSPITAL).**—This school, which is situated in Hunter Street, Brunswick Square, opens at the same time, and the periods of study, lectures, &c., are similar to those at the ordinary medical schools. A dissecting-room, physiological, chemical, biological, physical, and pharmaceutical laboratories, and library are provided at the School, and clinical lectures are regularly delivered at the Royal Free Hospital close by, which institution is appropriated to the students at the School as a field of practical study; clerkships, dresserships, being tenable there without fee by women.

**Scholarships, &c.**—Entrance Scholarships of £30. The St. Dunstan's Medical Exhibition, value £60 a year for three years, extendible to five years. Bostock Scholarship, £60, for two or four years, given on the result of the Preliminary Scientific Examination of the University of London. The John Byron Scholarship of £20 a year for four years, the Stuart Mill Scholarship of £30 a year for four years, the Fanny Butler Scholarship of £14 10s. a year for four years are offered from time to time. The Mabel Webb Research Scholarship, value £30 for two years, for research work in chemistry, physiology, or pathology. The Helen Prideaux Prize of £50 is offered every other year to graduates of the School. Prizes of £10 each are awarded in the classes of anatomy and physiology. Three Evans Prizes of £3 3s., £2 2s., and £1 1s. respectively are given in the midwifery class, and two Durham Prizes of £5 and £3 are given in the gynaecology class every second year. A prize of £5 is given in alternate years in the midwifery and gynaecology classes. An Evans Prize of £5 5s. is given for operative midwifery. Two Mackay Prizes of £20 each are offered annually. There are other scholarships for ladies willing to qualify themselves as practitioners in India. There is also a small fund from which assistance can occasionally be given to students who specially require pecuniary help.

**Fees.**—The fee for the ordinary curriculum of clinical lectures is £90 if paid in one sum, or £95 if paid in instalments. The fee for clinical teaching is £35, or £40 if paid in instalments.

Special Classes for the Preliminary Examination of the University of London. For the whole course, 20 guineas.

### EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

**COOK'S MEDICAL SCHOOL.**—This school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year; these have special advantages both as regards anatomy and physiology, at charges but slightly in excess of current rates. By decision of various examining bodies gentlemen rejected at their anatomical and physiological examinations (second conjoint, &c.) can get signed up for the supplementary work they are required to put in before re-examination. The school is also recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The surgical operations are performed on the dead body, and these courses are recognised for army examinations, the Indian Medical Service, &c. The school possesses a good collection of physiological and chemical apparatus, and gentlemen preparing for the higher examinations, the F.R.C.S.Eng., M.B.London, Cambridge, Oxford, &c., receive special instruction in the more difficult subjects by separate classes.

**LONDON SCHOOL OF DENTAL SURGERY.**—This institution is the oldest of the Dental Colleges in the United Kingdom, and its teaching is recognised by the Royal College of Surgeons for the dental diploma. It is centrally situated in Leicester square, is open daily, and under the supervision of a special staff and house surgeon. The mechanical laboratory is the most perfect of its kind, and its usefulness can hardly be over-estimated. The Hospital having been rebuilt during the past year the accommodation is equal to all requirements. Four demonstrators have been appointed to instruct the new students in the elements of operative dental surgery, and at the beginning of the session each demonstrator gives a course of lectures on this subject. There is the Saunders Scholarship and Walker Scholarship (entrance) value £20 each, awarded yearly, and the eight house surgeons are filled by students of the hospital holding the L.D.S. Fee for two years' hospital practice required by the curriculum including lectures, £50. The fee for three years' tuition in mechanical dentistry is 150 guineas.

**NATIONAL DENTAL HOSPITAL.**—This institution is situated in North-West London (Great Portland-street), and the same teaching facilities and hospital practice are obtainable here as at the foregoing institution, special demonstrations being given by members of the staff daily. There are also a mechanical laboratory, students' common room, a metallurgical laboratory, extraction and stopping rooms, students' hall, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools on October 1st. The medical tutors hold special classes before each College examination. The prizes include one entrance exhibition, value £15, and the Bymer prize of £5 5s. The fee for two years' hospital practice required by the curriculum, including lectures, is £40.

**LONDON SCHOOL OF TROPICAL MEDICINE.**—This institution is the outcome of a suggestion by the Right Hon. Joseph Chamberlain, H.M. Secretary of State for the Colonies, and is situated at the Royal Victoria Docks, in connection with the Seamen's Hospital, than which no more suitable spot could be found, as ships arrive there in greater numbers than elsewhere from all parts of the Tropics, affording immediate opportunity for the treatment of patients and for the study of tropical diseases. The school buildings are placed within the hospital grounds, and systematic courses of instruction are obtainable from duly authorised teachers throughout the year. Students also have the privilege of attending the medical and surgical practice at the Dreadnought Hospital, Greenwich. Information as to fees, &c., can be obtained of the Dean or the Secretary.

**UNIVERSITY EXAMINATION POSTAL INSTITUTION.**—This is an Institution conducted by Mr. E. S. Weymouth, M.A. (27, Southampton Street, Strand), which

offers special courses of lessons through the post for the M.D. (London or Durham), D.F.H. (Cambridge, London, &c.), and the F.R.C.S. (Eng. or Edin.). The tutors have the M.D. or M.S. degree. Two are gold medallists.

Medical students are admitted to the practice at the following metropolitan hospitals, to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

**WEST LONDON HOSPITAL, Hammermith.**—This contains over 160 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house-surgeons and two house physicians are elected every six months. Special departments have recently been opened for diseases of the throat, ear, skin, and deformities. An electrical department has also been added.

**GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.**—This institution has been recently enlarged, and now contains 159 beds. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

**BETHLEM ROYAL HOSPITAL.**—Two Resident House Physicians who have recently obtained their diplomas to practise medicine and surgery, are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee.

**NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen's Square, W.C.**—Contains 200 beds. It has on its staff men of European reputation, and the Institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 320 beds in the two buildings. There are four house physicians, who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at 4 o'clock, save during the vacations. Pupils are admitted to the practice of the hospital. Terms, £3 3s. for three months; six months, £5 5s.; perpetual, £10 10s.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.**—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

**CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road,** contains seventeen beds, with an extensive out-patient department recently enlarged. Clinical demonstrations and instruction to qualified practitioners and senior students daily during the hours of the surgeon's visits. Twelve clinical assistants who must be duly qualified are elected to assist the surgeons. Operation days—in-patients, Tuesdays, 2.15 p.m.; out-patients, Tuesdays and Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months, £5 5s. Full details of this institution will be found on reference to our advertising columns.

**HOSPITAL FOR DISEASES OF THE THROAT AND CHEST, Golden Square, W.,** with branches at Newington, Walworth and Notting Hill, contains 50 beds. Students are admitted to hospital practice on payment of fee of three months' course, £3 3s.; for six months, £5 5s.; perpetual, £7 7s.

**THE HOSPITAL FOR WOMEN, Soho Square.**—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynaecology, open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, £5 5s.

**THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street, W.,** offers excellent opportunities for clinical study and training in the details of operative gynaecology. The success of the staff in this department have gained for them an European reputation. There are 47 beds.

**HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen's Square, and Cromwell House, Highgate.**—Fee for three months' attendance, £3 3s.; perpetual, £5 5s. There are now 200 beds, besides 52 additional at the convalescent branch, and it is probably the largest institution of the kind in the world. The practice of the hospital has been thrown open gratuitously to pupils of the different hospitals and medical schools of London, on conditions to be ascertained from the secretary.

**ROYAL LONDON OPHTHALMIC HOSPITAL (formerly in Moorfields, rebuilt during the present year in the City Road),** is the largest hospital devoted to this specialty in Great Britain, and contains 131 beds. Students and practitioners are admitted to the practice daily at nine o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the secretary.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, Charing Cross,** has about 84 beds, and a very large out-patient clinique. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

**ROYAL EYE HOSPITAL, St. George's Circus, Southwark.**—There are 40 beds and 2 cots. Fees £2 2s. for 3 months, £3 3s. for 6 months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction and diseases of the eye; fee £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

**ST. PETER'S HOSPITAL FOR STONE.**—This is the only special hospital for the treatment of stone and genito-urinary diseases in the United Kingdom. It contains 27 beds and one private ward, and has an excellent record. Students are admitted on the usual terms.

**LONDON TEMPERANCE HOSPITAL.**—The hospital contains 110 beds. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

**METROPOLITAN HOSPITAL, Kingland.**—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

**SKIN HOSPITALS.**—"St. John's Hospital for Diseases of the Skin." Out-patient department, 49, Leicester Square; In-patient Department, 288, Uxbridge Road. This hospital has now a well-equipped in-patient department, with 50 beds. A School of Dermatology in connection with the hospital was opened last April, and conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence in October next, and the dates and times will be duly announced in our columns.

One of the oldest institutions of the kind is the Western Skin Hospital, which was started as long ago as 1851. In recent years the number of patients has greatly increased. The practice of the hospital is open to students and practitioners. Students of this specialty have also the "London Skin Hospital," in Fitzroy Square, with seven beds and an out-patient depart-

ment of over 1,400. There is also the Stamford Street Skin Hospital, in the southern part of the metropolis, with 10 beds and an out-patient department of 5,600, so that the students' needs in this direction are well catered for.

## PROVINCIAL MEDICAL SCHOOLS.

**BRISTOL UNIVERSITY COLLEGE.—FACULTY OF MEDICINE.**—This is the only medical school in the West of England. The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothecaries' Society of London, and for the examination of the Army and Navy Boards. It is now arranged that students of the college shall be admitted to the clinical practice of the Bristol Royal Infirmary and the Bristol General Hospital conjointly, and consequently both these institutions are open to all students. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments. Special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 28 beds. The total number of beds available for clinical instruction is therefore 602. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

**Appointments.**—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers.

Clinical lectures are given regularly at both institutions.

**Scholarships, Prizes, &c.**—Prizes and certificates of honour are given in University College in all the subjects of the curriculum, open only to perpetual students. There are two entrance scholarships, value £50 and £30 respectively, two Martyrs' memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbit's memorial prize, value £9, for proficiency in practical surgery, one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

**Fees.**—School fees for attendance on all courses of lectures, except comparative anatomy, 65 guineas, or 55 guineas. Dental composition fee, 55 guineas. Clinical fees—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual medical and surgery, 35 guineas; clerk or dresser, 5 guineas; obstetric clerk, 3 guineas.

Prospectus and further information on application to the Dean, Professor E. Markham Skerritt.

**YORKSHIRE COLLEGE SCHOOL OF MEDICINE, LEEDS.**—This school, which was founded seventy years since as the Leeds Medical School, forms the medical department of Yorkshire College, one of the colleges constituting the Victoria University. Students of the Yorkshire College are therefore eligible for the degrees of the Durham and Edinburgh Universities, and for the ordinary diplomas. The building erected on a site contiguous to the infirmary, and opened five years ago, contains one of the finest dissecting rooms in the kingdom, extensive laboratories for physiology and pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other

appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken; besides the infirmary there are a large dispensary, a large hospital for infectious diseases, and a hospital for women and children, all of which are open to students of the school.

Students here have also excellent opportunities of acquiring a thorough insight into psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, whereat lectures on mental diseases are delivered during the summer.

*Scholarships, Prizes, &c.*—(1) A Gilchrist scholarship of £50 a year for three years is awarded annually, and second biennially, to the candidate who stands highest at the June Preliminary Examination at the Victoria University, provided he passes in the first division. (2) A university scholarship of £50 is awarded annually on the results of the second examination for the degree of M.B. and B.Ch., held in March. (3) An entrance scholarship of 64 guineas (covering composition fee for a full curriculum of lectures) is offered every September to university students. There are also a Hardwick prize in clinical medicine, a M'Gill prize in clinical surgery, each of the value of £10, and Thorpe prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is 64 guineas for university students who have attended the preliminary scientific courses, and the same for non-university students, exclusive of chemistry and biology.

At the General Infirmary, containing 447 beds, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures, and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is also offered annually.

**UNIVERSITY COLLEGE LIVERPOOL (VICTORIA UNIVERSITY) MEDICAL FACULTY.**—New medical buildings are at present in course of erection, comprising departments of anatomy, surgery, anatomical museum, and laboratory and lecture room accommodation for the School of Dental Surgery, materia medica, toxicology, &c. These adjoin the physiological and pathological laboratories, which were recently built and equipped by the generosity of the Rev. S. A. Thompson-Yates, at a cost of over £30,000. The laboratories include theatres for physiology and pathology, laboratories for microscopic, physical and chemical physiology, for morbid anatomy, bacteriology, and chemical pathology, special rooms for research, &c., private rooms, students' common room and lavatories. The chemical rooms have been extended, so as to provide (*inter alia*) more complete accommodation for medical students and those engaged in laboratory work for diploma in public health. The Chair of Hygiene has secured adequate permanent accommodation in Ashton Hall, an institute adjacent to the college, which contains ample class-room and laboratory accommodation for study and research. The museums of anatomy, pathology, and materia medica are furnished with complete provision for the needs of students, and have recently been reorganised and revised. The museum of hygiene, accommodated in Ashton Hall, has been recently established on the lines of the Parkes Museum. It contains meteorological instruments and numerous models and specimens. Under the supervision of the professor of hygiene a course of lectures on sanitary science is given during the winter, suitable for candidates for sanitary inspectors' certificates.

**ROYAL INFIRMARY.**—The Royal Infirmary, which adjoins the school, contains 300 beds, with 40 special beds for the treatment of diseases of women. The Lying-in, Eye and Ear, Women's, Children's, Dental and Skin Hospitals are in the immediate vicinity, and their practice is open to the students of the medical faculty.

*Fees.*—The composition fees are £24 15s. for preliminary scientific classes; £60 for the medical classes required for the Victoria, London, and other University degrees; £70 for all the classes required for the diplomas

of the Conjoint Boards. The medical composition fees are payable in two instalments, at intervals of twelve months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

*Appointments.*—Three house surgeons, three house physicians, and one extern house surgeon to the Thornton Wards are appointed for six months, after (if necessary) competitive examination. Candidates must have a legal qualification. Clinical clerks for each physician, dressers for each surgeon, and clerks to the Thornton Wards for diseases of women are appointed every three months. Post-mortem clerks are appointed for six weeks. All students are required to perform this duty before the schedule for the final examination is signed.

*Fellowships and Scholarships.*—Fellowships, scholarships, and prizes of over £600 are awarded annually. (a) A Holt Fellowship in pathology and surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the pathological department. (b) A Holt Fellowship in physiology, awarded under similar conditions, of the value of £100 for one year. (c) A Robert Gee Fellowship in anatomy, awarded under similar conditions, also of the value of £100 for one year. (d) An Alexander Fellowship for research in pathology, of the annual value of £100, renewable. (e) A Johnston Colonial Fellowship in pathology and bacteriology (£100 a year, renewable). (f) A John W. Garrett International Fellowship in physiology and pathology (£100 a year, renewable). (g) Two Lyon Jones Scholarships, of the value of £21 each for two years, are awarded annually; a Junior Scholarship, open at the end of the first year of study to Victoria University students, in the subjects of the First M.B. Examinations; and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, on the subjects of anatomy, physiology, and therapeutics. (h) The Derby Exhibition of £15 for one year is awarded in clinical medicine and surgery in alternate years. Students may compete in their fourth and fifth years; in 1901 the subject will be clinical surgery. (i) The Torr gold medal in anatomy, and the George Holt medal in physiology, the Fletcher prize in physiology (£3 3s. in books), the Kanthack medal in pathology, the Robert Gee book prize, of the value of £5, for children's diseases, and numerous class prizes are awarded annually.

*Entrance Scholarships.*—Four Robert Gee Entrance Scholarships of the value each of £25 for one year are offered annually for competition. The holder is required to take out the science course for the University degree in medicine.

Communications should be addressed to the dean, Professor Paterson, M.D., University College, Liverpool.

**SCHOOL OF DENTAL SURGERY.**—A new mechanical laboratory has recently been erected at the Dental Hospital; it is adequately equipped with all modern appliances, and is under the charge of a skilled mechanic. The fees for dental education are £50 (payable in two instalments) for the Medical School curriculum; £21 payable on entrance, for two years Dental Hospital practice; £10 10s. for general hospital practice (two winters). A limited number of apprentices are taken at the hospital: fee (for three years) £105. Numerous scholarships and prizes are offered; (a) a Fletcher Scholarship of £21 in mechanical dentistry; (b) a Phillips Scholarship of £10 10s. in dental surgery; a Council Prize for dental mechanics (£5 5s. in books); Ash's Essay Prize (£2 2s.), &c.

Prospectuses and further information may be had on application to the Registrar, University College, Liverpool.

**MANCHESTER.—OWENS COLLEGE SCHOOL OF MEDICINE, VICTORIA UNIVERSITY.**—The medical school buildings, which include large laboratories, dissecting-rooms, library and reading rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished

laboratories. The buildings were extended only a few years ago, but owing to the rapid growth of the school further large additions have been made, including lecture theatres and laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

**Appointments.**—The following appointments are made in connection with the Manchester Royal Infirmary: Surgical registrar, at £80 per annum; a pathological registrar, at £100 per annum; a medical registrar, at £70 per annum; two assistant medical officers, each at £80 per annum; a resident medical officer at the Convalescent Hospital, Cheadle, one year £150 per annum; resident medical officer, one year, £150; resident surgical officer, one year, £150 per annum; two chloroformists, annually, at £50; two house surgeons and one house physician are appointed every three months for a term of six months; a resident assistant at the Convalescent Hospital, Cheadle, appointed every six months.

**Scholarships.**—Dalton Entrance Scholarships, £40 per annum, for two years; Cartwright Entrance Scholarship, £35 per annum, for three years; Hulme Entrance Scholarship, £35 per annum, for three years; Rogers Entrance Scholarship, £40 per annum for two years; Eaton Entrance Scholarship, £40 per annum for two years; James Gaskill Entrance Scholarship, £40 per annum for two years; Kay Shuttleworth (Sir Jas. Philips) Scholarship, £30 per annum for three years; Theodores Modern Languages Exhibition, £15; Honorary Research Fellowships; Manchester Grammar School Scholarship, £18 per annum for three years; Turner Scholarship of £20 to students who have completed four years of study in the College; Platt Physiological Scholarship, value £50, tenable for two years, open to students between the ages of 18 and 25; two Platt exhibitions, £15 each, for first and second year's students in physiology; Sidney Benschaw Physiological Exhibition, £15; Dumville Surgical Prize, £15, at the end of the winter session; two Dauntsey Medical Entrance Scholarships, value £35, tenable for one year; John Henry Agnew Scholarship in Diseases of Children, value about £30 awarded annually; Gilbert Scholarships of £50 per annum tenable for three years in any of the Colleges of the Victoria University, awarded annually to the candidate gaining the highest number of marks in the first division of the Preliminary Examination of the Victoria University; the Bradley Memorial Scholarship, £20, in Clinical Surgery is offered annually in the summer session to candidates who must be fourth year students; one Medical and one Surgical Clinical Prize are also offered annually.

**Fees.**—Composition fee, £70, in two sums of £35 each, Hospital practice: composition fee, £40, or two instalments of £25 each.

**Dental Fees.**—Composition fee, £50, payable in two sums of £25 each. Hospital practice, £21.

**SHEFFIELD UNIVERSITY COLLEGE MEDICAL DEPARTMENT.**—The medical department contains a medical library, good class-rooms, an excellent anatomical department, and every provision for medical education under the most modern principles. The physiological department has been entirely reconstructed and equipped in memory of the late president of the school. Mr. Wm. F. Favell, through the generosity of anonymous donors. The department consists of a lecture and demonstration theatre, students' laboratory, preparing room and galvanometer room, all of which are equipped with the most modern apparatus. New premises have been acquired near the College for the pathological museum and laboratory, and also for a bacteriological laboratory, which has been completely equipped through the generosity of "A Sheffield Citizen." The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. Full courses of instruction required for the D.P.H. are given. The new dental department has been recognised by the examining bodies. Students at this college obtain medical and surgical practice at the Royal Infirmary, a well-appointed institution, containing 240 beds, and also at the

Sheffield Royal Hospital, containing 125 beds. The fees for attendance, £6 6s. each for medical and surgical practice during the winter session, and for three months £3 3s. each. Perpetual fee for medical and surgical hospital practice in a single payment of £45, or in two payments, viz., £26 on entrance, and £22 within twelve months afterwards. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the City Fever Hospitals, and to the South Yorkshire Lunatic Asylum at Wadale. The winter session will commence on October 1st, when the introductory address will be delivered by Sir Thomas Barlow, Bart.

**Scholarships, &c.**—An entrance scholarship of the value of £110 is annually awarded to the best candidate (if of sufficient merit) in mathematics, elementary physics, inorganic chemistry, Latin, English.

Composition fee, 60 guineas, or in two instalments of 35 guineas and 30 guineas for lectures and practical classes required by the Examining Board in England.

The Kaye scholarship, for second year's students, natives of Sheffield, is awarded annually, under certain regulations. Prizes for clinical medicine and clinical surgery of 10 guineas; Simon prize in pathology, £10; prizes in books and certificates awarded annually.

**UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.**—A very commodious and ornate new building has been erected here at a cost of about £31,000. The electric light is installed throughout the whole of the working part of the college. The Royal Infirmary, at which clinical instruction is obtained, contains 280 beds. Pathological demonstrations are given as opportunity offers. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, Children's Hospital and Northumberland County Lunatic Asylum. Lectures are given on psychological medicine and public health.

**Appointments.**—Assistant demonstrators of anatomy receiving each an honorarium; prosectors for the professor of anatomy, assistant demonstrators of physiology and pathology, assistants to the dental surgeon, clinical clerks, and dressers are appointed at regular intervals. One year's attendance at the College is required on the part of candidates for the degrees in medicine of the University of Durham.

**Scholarships, &c.**—University scholarships, value £100, for proficiency in arts, awarded annually at the beginning of winter session to full students in their first year only. The Dickinson memorial scholarship (value, the interest of £400 with a gold medal) for medicine, surgery, midwifery, and pathology, open to full students who have passed the primary examination of a licensing body. The Tulloch scholarship, interest of £400 annually, for anatomy, physiology, and chemistry. The Charlton memorial scholarship, interest of £700 annually, open to full students entered for the class of medicine at end of the fourth or fifth winter. The Gibb scholarship, interest of £500 annually, for pathology, at end of summer session. Goyder memorial scholarship in clinical medicine and clinical surgery, proceeds of £325 annually. The Luke Armstrong memorial scholarship, interest on £680. The Stephen Scott scholarship in surgery, interest on £1,000. The Heath scholarship in surgery (the next award will be in 1902); the interest on £4,000 is awarded every second year. The Gibson prize in midwifery and diseases of women and children; the interest on £225 is awarded yearly. At the end of each session a prize of books is awarded in each of the regular classes.

**Fees.**—(a) A composition ticket for lectures at the college may be obtained—1. By payment of 70 guineas on entrance. 2. By payment of 45 guineas at the commencement of the first sessional year and 35 guineas at the commencement of the second sessional year. 3. By three annual instalments of 35, 30, and 20 guineas, respectively at the commencement of the sessional year. (b) Fees for attendance on hospital practice: For three months' medical and hospital practice, 5 guineas; for six months, 8 guineas; for one year, 12 guineas; perpetual, 25 guineas; or by three instalments at the commencement of the sessional year, viz., first year 12 guineas; second year, 10 guineas; third year, 6 guineas; or by

two instalments, viz., first year, 14 guineas; second year, 12 guineas.

**UNIVERSITY COLLEGE, CARDIFF, SCHOOL OF MEDICINE.**—This college which is one of the colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893, Chairs of Anatomy and Physiology and a Lectureship in *Materia Medica* and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary, give students of the College the privilege of attending this large and well-ordered Hospital which is situated within five minutes walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the corresponding examinations, a student may proceed to London or elsewhere and complete his qualifying course for a university degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries may compound for their classes by paying a single composition fee of £40, or by paying £18 10s. and £24 10s. at the beginning of their first and second years respectively.

Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28 and £21 at the beginning of their first, second, and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

**Scholarships, &c.**—The attention of students about to matriculate is drawn to the numerous entrance scholarships for exhibitions which are offered at the college for competition in September, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar.

**LIVERPOOL ROYAL SOUTHERN HOSPITAL.**—The clinical school of this hospital is situated within convenient distance of the school of medicine, and affords every facility for clinical and pathological study. The hospital contains 200 beds, and in addition to the general medical and surgical cases attention is devoted to the diseases of women and children. There is a special ward for medical diseases in connection with the University College laboratories.

The medical and surgical staff visit the wards daily, and the ward instruction is supplemented by weekly clinical lectures. Additions have been made to the teaching staff so that students may now obtain instruction in diseases of the eye, ear and throat. Demonstrations in the use of the X-ray apparatus are given at intervals. There is an excellent pathological department, with laboratory attached, where demonstrations are arranged for and regular instruction is given in practical pathology. The practice of St. George's Hospital for diseases of the skin is free to students, and thus ample opportunity is afforded for acquiring a knowledge of dermatology. In addition to the clinical

clerkships which are allotted to the students the resident posts of ambulance officers are given to the students whom the board may think most suited to hold them every three months. The Alexander Fellowship in Pathology of £100 a year is open to students of this school, three prizes of £5 each are also awarded to the gentlemen who present the best taken series of medical and surgical cases. Fees: perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.

There are rooms for a limited number of resident students; terms (exclusive of fee for hospital practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies.

**THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.**—The Liverpool School of Tropical Medicine has had another busy year, the chief item of interest being the despatch of further expeditions for the purposes of medical research. In March, 1900, Dr. Annett, Dr. Dutton, and Dr. Elliott were despatched to Nigeria (northern and southern), where they spent a considerable time in research work, and have published an important report on the subject. In June the Yellow Fever Expedition, consisting of Dr. Durham and Dr. Walter Myers, were despatched to Para in Brazil, and has not yet returned. One member of the expedition, Dr. Walter Myers, unfortunately lost his life in the performance of his duties, from a fatal attack of yellow fever, contracted whilst conducting an autopsy. The latest expedition of the school is that recently despatched under Major Ross, F.R.S., and Dr. Logan Taylor to Sierra Leone to conduct most important experiments there with a view to exterminating mosquitoes, if possible. In memory of Dr. Walter Myers, the school have founded a Walter Myers' Chair of Tropical Medicine and a Walter Myers' Fellowship of Tropical Medicine, to which Major Ross, F.R.S., and Dr. J. E. Dutton have respectively been appointed. Drs. Fielding Ould, Grunbaum, and Balfour Stewart have been appointed assistant lecturers to the school. No difficulty has been experienced in raising all the money required for the expenses of the school, although these are extremely heavy.

**BRISTOL ROYAL INFIRMARY.**—This is one of the largest provincial hospitals in Great Britain, and contains 270 beds. It is provided with all the necessary appliances for a complete clinical education. The resident appointments are five in number, the two juniors of which are each tenable for six months, and are intended for qualified students of the infirmary, who have previously acted as medical and surgical registrars. Several scholarships and prizes are obtainable. Fees for admission to the medical practice, six months, 7 guineas; twelve months, 12 guineas; perpetual, 20 guineas. The same fees are payable for surgical practice. Perpetual fee for medical and surgical practice, 35 guineas. Dental practice, one year, £7 7s.; perpetual, £12 12s.

The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached:—

**BATH ROYAL UNITED HOSPITAL.**—This is a well-appointed hospital in the West of England, with 120 beds, at which students can obtain clinical instruction. The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months' ten guineas.

**BRADFORD INFIRMARY.**—The hospital contains 210 beds. Non-resident pupils are received—and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

**BRIGHTON SUSSEX COUNTY HOSPITAL** contains 178 beds. It is recognised by the College of Surgeons and by the Conjoint Board. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years.

**NORFOLK AND NORWICH HOSPITAL.**—This hospital is recognised by the Colleges, and contains 220 beds. Fees,

£10 10s. for six months', £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

LIVERPOOL NORTHERN HOSPITAL, contains 180 beds. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.; practical pharmacy, £2 2s.

NORTHAMPTON GENERAL INFIRMARY.—The number of beds is 163. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in anatomy and materia medica and practical pharmacy. Non-resident pupils are taken at a fee of £10 10s.

THE ROYAL HOSPITAL, Portsmouth.—The hospital is a preparatory school of medicine and surgery, and the attendance of pupils is recognised by the Examining Boards. The number of beds is 150, and during last year there were 1,303 in-patients and 9,191 out-patients.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 218 beds (including special children's wards), and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the Examining Boards. Arrangements can be made by which students can attend midwifery on application to the House Surgeon.

WOLVERHAMPTON GENERAL HOSPITAL.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. Fees: Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

#### THE ENGLISH UNIVERSITIES.

The English Universities are six in number, viz., Oxford, Cambridge, London, the Victoria, Durham, and the recently created University of Birmingham. The choice of a university is usually determined by social, geographical, and financial considerations. Evidently students whose parents are able and willing to incur the necessary expense would do well to select one or other of the ancient universities for the possession of their degrees, which invest their holders with a status not accorded by the public to the degrees of equally efficient but more modern educational institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers free scope, and its degrees are recognised as the outward and visible proof of high professional attainments untrammelled by the traditions which hamper the older bodies. The Victoria University comprises Owens College, Manchester, University College, Liverpool, and the Yorkshire College at Leeds. It thus covers a wide area and attracts considerable numbers of students whose aim is essentially the possession of a degree in medicine. Durham University has "gone ahead" of late years, and has done much to facilitate graduation by the abolition of irritating and futile restrictions without sacrificing the ideals of university training.

#### OXFORD.

There are two degrees in medicine, M.B. and M.D., and two degrees in surgery, B.Ch. and M.Ch. The M.B. and B.Ch. degrees are granted to those members of the University who have passed the second examination. Graduates in Arts, B.A., are alone eligible for these two degrees. In order to obtain the degrees of M.B. and B.Ch., the following examinations must be passed:—1. Preliminary subjects: Mechanics and physics, chemistry, animal morphology and botany. 2. Professional (a) First Examination (held twice a year): Subjects: Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the

Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy and Materia medica with Pharmacy. (b) Second Examination: Subjects: Medicine, Surgery, Midwifery, Pathology, Forensic medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, physics, and chemistry, December and June; Animal morphology and botany, December and March; Professional (First and Second M.B.), June and December.

The degree of M.D. is granted to Bachelors of Medicine of the University who have entered on their thirtieth term on their presenting a dissertation approved by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June, at the end of the Second M.B. Examination.

The First Examination for the degrees of M.B. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be passed together.

The Second Examination may be passed at any time after the completion of the first. The subjects of medicine, surgery, and midwifery must be passed at the same examination, but candidates are allowed to present themselves in pathology at a separate examination.

*Diploma in Public Health.*—An examination is held yearly in Michaelmas Term, open to all registered medical practitioners. No one is admitted as a candidate unless his name has been on the "Medical Register" for twelve months.

*Scholarships, &c.*—Scholarships in some branch of Natural Science (chemistry, physics, biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as exhibitions of less annual value, are awarded after competitive examinations every year by some of the Colleges. Notices of vacancy, &c., are published in the "University Gazette." In February there is competed for annually, by those who, having obtained a first-class in any school (moderations or final), or a scholarship or prize open to general competition in the University, have passed all the examinations for the degree of B.A. A Radcliffe Travelling Fellowship is tenable for three years, of the annual value of £200. The examination is partly scientific, partly medical. A Rolleston Memorial prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some biological subject including physiology or pathology.

More detailed information may be obtained from the University Calendar and from the Registrar.

#### CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the university, and have passed the "previous" examination in classics and mathematics. There are three examinations: the first in chemistry, physics, and biology; the second in human anatomy, physiology, and (2) pharmaceutical chemistry; and the third, in the usual practical subjects with hygiene and pathology; each examination is divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in Surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine. The M.D. degree may be taken three years after the

**M.B.** An Act has to be kept, with oral examinations, and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submit original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150. to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses &c. Non-collegiate students have only to pay the University fees which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University degree grants a diploma in public health without the necessity of residence, the examination being in so much of State medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the Medical Register of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar.

#### UNIVERSITY OF LONDON.

**The Matriculation Examination.**—Candidates for any degree in this University must have passed the matriculation examination. It is held twice in each year—on the second Monday in January and the second Monday in June; and may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies.

**The Preliminary Scientific M.B. Examination.**—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M.B. degree. The subjects are (a) chemistry and physics, (b) general biology. The examination takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates only, commencing on the third Monday in January.

**Intermediate Examination.**—The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. The subjects of the examination are anatomy, physiology and histology, organic chemistry, materia medica, and pharmaceutical chemistry. No candidate shall be admitted to this examination unless he is nineteen years of age and has passed the Preliminary Scientific Examination at least two years previously. Fee for this examination, £5.

**M.B. Examination.**—This examination is held for Pass and Honours in October, and for Pass only in May. The candidate must have passed the Intermediate Examination at least twenty-one months earlier, must have attended lectures and hospital practice in a recognised medical school for two years, including at least two months' attendance on lunacy and infectious diseases, one of which must be subsequent to the Intermediate Examination, must have conducted at least twenty labours, and have acquired proficiency in vaccination.

**Bachelor of Surgery.**—The examination for the degree of Bachelor of Surgery takes place once in each year, in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in

operative surgery, and of having operated on the dead subject. The subjects of the examination are surgery (including operations on the dead body), pathology, and surgical anatomy. Fee, £5

**Master in Surgery.**—The examination for the degree of Master in Surgery takes place once in each year, in December. Candidates must be bachelors of surgery of at least two years' standing; one year is, however, remitted in the case of candidates who passed the B.S. examination in the first division. The examination comprises mental physiology, surgery, and surgical anatomy.

**Degree of Doctor of M.D.—Doctor of Medicine.**—The degree of Doctor of Medicine is granted after examination to bachelors of medicine of at least two years' standing. The examination comprises medical physiology and medicine, and is conducted by written papers, clinical examination, and *viva voce*. A candidate who presents a thesis approved by the examiners is excused the written examination.

**Doctor of Medicine in State Medicine.**—This degree is granted to bachelors of medicine after examination on producing evidence of having been engaged in the study of State Medicine for at least two years. The examination is the same as for the ordinary M.D., with the exception that State Medicine takes the place of medicine.

**Prizes.**—1. The Sherbrooke Prize is awarded triennially for the best essay, embodying original research in some branch of science.

2. The Granville Prize is awarded in each of the two years intervening between the several awards of the Sherbrooke Prize.

Exhibitions or scholarships are awarded to the first six candidates in honours at the matriculation examination, and, if thought proper, to the first candidate in honours at the other examinations.

#### UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred, viz., the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are: Elementary anatomy and elementary biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medical jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine, and psychological medicine, surgery, and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Infirmary, Newcastle-upon-Tyne.

Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examination of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of

Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of bachelor in surgery, in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the military or naval services, or in medical and surgical practice.

Each candidate must prepare an essay, which must be type written, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar 1901-2.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

#### VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds. Candidates for degrees in medicine and surgery must attend, during at least two years, classes in one of the colleges of the University.

The degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for degrees in medicine and surgery are required to pass the Preliminary Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Preliminary Examination are—1, Latin; 2, Elementary Mathematics; 3, Elementary Mechanics; 4, English; 5, one of the following:—(a) French; (b) German; (c) Greek; (d) Italian (e) Spanish; (f) any other modern language, permission to present which has been obtained from the Board of Studies. Notice of intention to present either Italian or Spanish must be given before March 1st in each year.

Before admission to the degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities.

All candidates for these degrees must pass three examinations, namely—the First examination; the Second examination; and the Final examination.

**First Examination.**—The subjects of the examination are, 1, Chemistry; 2, Elementary Biology; 3, Physics.

Candidates must have attended, during at least one year, courses of both lectures and laboratory work in each of the above-named subjects.

**Second.**—1, Anatomy; 2, Physiology (including physiological chemistry and histology); materia medica, and pharmacy.

Candidates must have passed the First Examination, and have attended courses of instruction in anatomy (systematic and practical) during two winter sessions and one summer session, in physiology for two winter sessions, in materia medica and pharmacy for one summer

session. Candidates may present themselves separately in (a) anatomy and physiology, (b) materia medica and pharmacy.

**Final.**—The examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B. or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the final examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the second examination are admitted to it. The regulations relating to the M.D. and Ch.M. degrees can be obtained on application to the Registrar.

**Fees.**—Preliminary examination, £2; for any subsequent examination, £1; First examination, £5; for any subsequent examination, £2. The fees for the second examination, for the final examination, and for the examination for the degree of Ch.M. are the same as for the first examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £4 on the conferring of the degree of Ch.M.

The Preliminary examination is held in June and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The second and final examinations are held in March and July, the examination for Ch.M. in July only.

#### UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of public health. In order to obtain any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the university.

**Degrees of Bachelor of Medicine and Bachelor of Surgery.**—The student must have passed either the matriculation examination of the university or one of the following examinations, which will be accepted in lieu thereof for the present:—(a) The previous examination of the University of Cambridge. (b) Responsons of the University of Oxford. (c) The matriculation examination of any other university in the United Kingdom. (d) The leaving certificate (higher) of the Oxford and Cambridge Boards. (e) The Oxford or Cambridge junior local examinations (first or second class honours). (f) The Oxford or Cambridge senior local examination (honours). (g) The College of Preceptors examination for first class certificate.

Matriculation examinations are held in June and September each year.

**Degrees of Doctor of Medicine and Master of Surgery.**—Candidates for either of these degrees will be required either—(a) To present a thesis embodying original observations in some subject embraced in the medical curriculum and approved by a Board of Medical Examiners; or (b) to pass a general examination (written and practical) in medicine or surgery, according to the degree desired. The University also grants degrees in public health and in dentistry, for both of which amply provision has been made.

**Dental Department.**—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

**THE GENERAL AND QUEEN'S HOSPITALS.**—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 6,000 in-patients

and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Windle, Dean, Medical Faculty.

### THE ENGLISH COLLEGES.

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma in medicine, surgery, and midwifery.

CONJOINED EXAMINING BOARD IN ENGLAND (ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND).

Any candidate who desires to obtain both the above licences is required to complete five years of professional study at recognised medical schools and hospitals, and to comply with the following regulations and to pass the examinations hereinafter set forth.

*Professional Examinations.*—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to the Secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the first professional examination are—Chemistry and physics, practical pharmacy, and elementary biology. A candidate may take this examination in three parts at different times. A candidate will be admitted to examination in chemistry and physics and elementary biology before registration as a medical student by the General Medical Council, and he may take pharmacy at any time during the curriculum. Rejection entails a delay of not less than three months from the date of rejection, and the candidates will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a university in the United Kingdom, India, or in a British colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students, and after the lapse of not less than nine months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he had pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine, and

public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and diseases peculiar to women. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follows:—For the whole examination, £15 15s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and diseases peculiar to women, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

*Licentiates.*—Candidates are now subject to the regulations of the Conjoint Examining Board in England.

The following by-laws, amended in conformity with the revised regulations of the Conjoint Examining Board, were re-enacted as follows:—

"Every candidate for the college licence (unless specially exempted) shall be required to produce satisfactory evidence of having passed before the commencement of professional study a preliminary examination on subjects of general education recognised by the college.

"Every candidate shall be required to produce satisfactory evidence of having completed five years of professional study, after passing a recognised preliminary examination before admission to the final examination.

"A candidate shall not be admitted to the second examination until the completion of two winter sessions and one summer session (or 15 months during the ordinary sessions) at a recognised medical school, nor until the expiration of one winter and one summer session after passing Parts I. and III. of the first examination.

"A candidate shall not be admitted to the third (or final) examination till the expiration of five winter and five summer sessions from the date of passing the preliminary examination and of four winter and four summer sessions after passing Parts I. and III. of the first examination, and of two winter and two summer sessions after passing the second examination."

*Members.*—The membership of the college is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised university are admitted to a pass examination, but others must have passed the examinations required for the licence of the college. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British university, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 15s. is deducted. In either case £6 6s. has to be paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

**Membership.**—The candidates are now subject to the regulations of the Conjoint Board.

**Fellowship.**—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the college before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised universities of not less than four years' standing.

**Fees.**—At First Examination: Members, £5 5s.; non-Members, £10 10s.; £5 5s. returned if rejected. At Second Examination: Members, £10 10s.; if not a Member £21. In the latter case £10 10s. is returned in case of rejection. Further information can be obtained on application to the Secretary of the Royal College of Surgeon, Lincoln's Inn Fields, London, W.C.

SOCIETY OF APOTHECARIES OF LONDON.

**Primary Examination.**—This examination consists of two parts: Part I.—Elementary Biology, Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids; Heat, Light, and Electricity; Practical Chemistry, Materia Medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The Final Examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.

Part I. includes:—Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes:—(a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynaecology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Sections 2.—This section consists of two parts.

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy.

Section 2 cannot be passed before the expiration of the fifth year.

**Fees.**—The fee for examination is £5 5s., total for the licence, £15 15s.; Re-examination—Primary for each Part, £3 3s.; Final, Sec. I. for each Part, £3 3s.; Final, Sec. II., for each Part, £3 3s.

Further information, with particulars as to the course of study, and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

The licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

THE Dental Hospital of London (Leicester Square) has received the sum of £500 from the executors of the late Richard Bowerman West, Esq.

Ireland.

THE IRISH MEDICAL SYSTEM.

THE system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital, and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter for the whole or any part of his course at any school or hospital he pleases. As might be expected, religion, social rank, and locality of residence have their influence in causing certain classes of students to resort to schools and hospitals suitable to their condition. But scholastic or collegiate regulations impose no restrictions as to the place of study, and as the school and hospital fees are paid in detail in Dublin, and not in a lump sum, as in London, the pupil is absolutely free to do as he pleases.

In London the student bargains with his hospital and schools, in the first instance, for a complete course of instruction, for which he pays, in whole or in part, in advance, and his entire study is conducted within the one institution. In Dublin, on the contrary, the student enters for hospital and for courses of study separately, and takes the courses at any school or hospital he pleases which "gives best value," migrating from one school or hospital to another as he thinks fit.

LODGING AND LIVING OF IRISH MEDICAL STUDENTS.

There is in Dublin no organisation for domestic accommodation of medical students, save for those who are passing through Trinity College, in whose case rooms and "commons" (i.e., dinner) are provided at fixed rates. Those who can afford to pay £6 6s. or £7 7s. per month for their lodging and maintenance may find accommodation in the family of some medical man who receives boarders, in which case they become members of the family for the time being, and subject to its discipline. The majority of Dublin students, however, take a lodging in some economical locality, or they "chum" with some other student for the purpose. It is usual to contract with the lodging-house keeper for board or partial board, but some students cater for themselves.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:—

COST OF MEDICAL EDUCATION.

School.	Cost.
School of Physic, Dub. Univ. ...	£119 14s.
Royal College of Surgeons, Dub. Univ., School ...	£124 10s.
Catholic University School ...	£124 19s.
Queen's Colleges... ..	£110 (?)

COST OF DIPLOMATA OR DEGREES.

Qualifying Body.	Cost.
Dublin University ... ..	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University ... ..	£15.
Conjoined Royal Colleges ... ..	£42.
Apothecaries' Hall ... ..	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £229 18s., according as the teaching of the Queen's Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred, the total will vary, say from £170 to £200. "Grinding" usually costs £5 5s. for each of the four examinations, but if a student needs private "grinding" in special subjects he must pay extra for them.

This sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they accrue, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion. If, on the other hand, he prefers to pay a lump sum down, he can "apprentice" himself to a teacher who will undertake all monetary responsibility for his education, and who may be able to give him some special advantage as his own pupil at hospital. This so-called "apprenticeship," is very generally a simple contract for the payment of fees, and involves but little of that special teaching which is due by a master to a true apprentice. All the Dublin schools require fees to be paid in advance.

#### DATE OF ENTRY.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be recollected that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

#### PRELIMINARY EXAMINATIONS.

The first work of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35, Dawson Street, Dublin. He is thereupon placed upon the Register of Medical Students (without fee) and his period of study counts from that date. He must register at the earliest possible moment, or he will lose credit for his work.

The only preliminary examination held specially for medical students is now held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, e.g., the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Education passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent. The Preliminary of the Dublin Colleges has been considerably increased in severity within the past three years, the examiners being now experts in education, and not necessarily members of the medical profession.

The Preliminary is held in March and September, in the subjects specified by the General Medical Council.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from the book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic; (b) algebra, including simple equations; (c) geometry, Euclid, Books I., II., and III., with easy deductions.

4. One of the following optional subjects:—(a) Greek, (b) French, (c) German. The books specified are:—1. English—Shakespeare, "Merchant of Venice" 2. Latin,—The first and second books of the "Æneid," or the "Jugurthine Wars," or the third book of Livy. 3. Greek—The first book of the "Iliad" or the first book of Xenophon's "Anabasis." 4. French—Fénélon's "Télémaque," Books I., II., III. German—Schiller's "Wilhelm Tell."

#### QUALIFICATION IN IRELAND.

THE Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes:—a. Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees b. Those who take the licence of the conjoined Royal Colleges of Physicians and Surgeons. c. Those who take the licence of the Apothecaries' Hall. d. Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. e. Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomata, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The Irish Licensing Bodies are as follows:—

#### THE UNIVERSITY OF DUBLIN.

THE University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and the higher degrees of M.D. M.Ch. and M.A.O. to those who have held for at least three years the grade of M.B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £64 1s.; Hospitals, £55 13s.; Degree Fees, £27.—£146 14s.

The expense of the B.A., amounting altogether to £83 4s., should be added, making the total cost £229 18s.

*Doctor of Medicine.*—In addition to its ordinary qualifications, the University grants the following higher degree of M.D. To obtain this the candidate must have obtained the degree of M.B., or qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Total fee for this degree, £13.

*Master in Surgery.*—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for the degree of Master in Surgery, £11.

*Master in Obstetric Science.*—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course in obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynecology, anatomy of female pelvis and elementary embryology, and clinical gynecology. Fee for the degree of M.A.O., £5.

*Diplomate in Medicine, Surgery, and Midwifery.*—The course and examination is the same as for the degree,

except that the lectures and examinations in botany and zoology need not have been taken out or passed, and that the candidate need not have obtained an Arts degree. Fee for the diploma in medicine, surgery, and midwifery, £21.

*Qualification in State Medicine.*—The candidate must be a M.D. of Dublin, Oxford, or Cambridge.

The candidate must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months, under an approved Officer of Health.

#### THE ROYAL UNIVERSITY OF IRELAND.

The Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, i.e., the matriculation examination of this University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees:—

M.B., M.D., B.Ch., M.Ch., B.A.O., M.A.O., a diploma in sanitary science; a diploma in mental diseases.

All degrees are open to persons of either sex.

The university examinations are held in the spring, beginning about May 1st, and in the autumn, beginning about September 24th.

All candidates for any degree must pass the matriculation examination and the first university examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the first university examination after one year from matriculation, fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each primary, £1; for the degree, £2; for the diploma, £10.

In addition the following degrees are granted:—*Diploma in Sanitary Science.*—Conferred only on graduates in medicine of the university of at least twelve months' standing. Fee, £2. *Subjects.*—Climatology, chemistry, geology, physics, vital statistics, hygiene, sanitary law.

*The M.D. Degree.*—Conferred only on graduates in medicine of the university of three years' standing. Fee, £5. The examination will comprise medical diseases and the theory and practice of medicine, including pathology.

*The M.Ch. Degree.*—Conferred only on graduates in medicine of the university of three years' standing. Fee, £5.

The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology.

*The Mastership of Obstetrics.*—Conferred only on graduates in medicine of the university of three years' standing. Fee, £5.

The examination comprises midwifery and diseases of women and children.

*Prizes, &c.*—First Examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

Second Examination in Medicine.—Two first-class of £25, and two second-class of £15.

Third Examination in Medicine.—Two first of £30 each, and two second of £20 each.

Medical Degrees Examination.—Two first of £40 each, and two seconds of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

#### ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

THE examinations held conjointly by the two Colleges are the inlet of most Irish students to the profession, especially of those educated in Dublin. The course, as in other bodies, extends over five years, with examina-

tions at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The five years may be described as—first, preparatory; second, theoretical; third and fourth, application of the theory to practical work; and, final, strictly practical in hospitals, general and special. The regulations are so voluminous that an epitome of them would be unsatisfactory, and we recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of "grinding" or of re-examination fees, which have to be paid in case the candidate fails to pass in all the subjects of his examination at the one time.

The conjoined Colleges also hold Preliminary Examinations in General Education, and confer a diploma in Public Health, of all of which information will be found in the following pages.

#### APOTHECARIES' HALL OF IRELAND (L.A.H.).

This body is authorised to grant a complete qualification in medicine, surgery, and midwifery, recognised and registrable under the Medical Act of 1886, and entitling the holder to occupy medical appointments in all the public services. It also confers the legal right to dispense medicines in Ireland. The examinations are held on the third Monday in January, April, July, and October, and the requirements in respect of studies will be approximately the same as those of the conjoint examinations of the Royal Colleges of Physicians and Surgeons in Ireland. The examination fees payable for the qualification of L.A.H. are as follows:—First professional, £5 5s., second, £5 5s.; third, £5 5s.; final examination, £6 6s.

The fees for re-examination are £1 1s. for each subject, excepting in the subjects of chemistry, pharmacy, surgery, and medicine, the fees for which are £2 2s.

The fee for final alone is £15 15s. Candidates may be admitted to a special examination under special circumstances, at an extra fee of ten guineas.

Candidates already on the Register will receive the diploma of the Hall on passing an examination in medicine, surgery, midwifery, and pharmacy, and paying a fee of ten guineas. If medicine or surgery are required two guineas extra will be charged. The candidate will be exempt from each of the above subjects, which are covered by his previous qualification or qualifications.

In addition to the qualifying diploma awarded by the above bodies there are diploma in special subjects awarded as well. These are the licence in Dentistry and the diploma in Public Health.

#### THE LICENCE IN DENTISTRY.

There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma, and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The Irish diploma in Dentistry is granted by the Royal College of Surgeons.

*Course of Study for the Licence in Dentistry.*—Candidates are required to pass three examinations, viz.:—Preliminary (in General Education), Primary Dental, and Final Dental.

The Primary Dental examination is in (1) Physics, (2) Chemistry, (3) Anatomy, (4) Physiology and Histology, (5) Surgery—all these subjects with special reference to dentistry. The examination fee is £10 10s. The Final examination is in (1) Dental Surgery—clinical and operative; (2) Dental Mechanics—clinical and practical, including metallurgy. The fee for this examination is, for a Licentiate of the College, £10 10s.; for any other candidate, £26 5s. Each of these examinations must be preceded by complete courses of study in these subjects.

**Exemptions.**—Candidates educated in England or Scotland are admitted to the examination on the production of the certificates that would be necessary for both Primary and Final examinations in their own countries. Furthermore, the College admits to examination, *sine curriculo*, candidates whose names are on the *Dental Register*, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application, accompanied by any certificate they may have of general or professional education, and by the required fee.

#### THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the conjoined Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and Architecture. (3) Sanitary Law and Vital Statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school.

In Ireland the number of teachers in this category does not exceed, at present, ten, but the recent Sanitary Order of the Local Government Board, which affords facilities for the creation of many additional superintendent medical officers of health, will not only supply the demand, but will stimulate the much-needed sanitary improvement in Ireland.

#### THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

**THE SCHOOL OF PHYSIC OF DUBLIN UNIVERSITY.**—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians. Some of the professors in the schools are *ex officio* medical officers of Sir Patrick Dun's Hospital. The school is freely accessible to all students, and the instruction provided occupies a high rank.

Every student of the school must be matriculated by the senior lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a university licence or degree, in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the entrance examination in Arts in Trinity College, the preliminary examinations of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council.

Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and institutes of medicine; the other in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in Medicine or in Surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Degree Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him, within two years from the time of obtaining the prize.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student

who, at the ordinary June half M.B. Examination, shall obtain highest marks in Physiology and Histology.

**THE ROYAL COLLEGE OF SURGEONS IN IRELAND. SCHOOLS OF SURGERY.**—By the amalgamation of the Carmichael College and the Ledwich School with the School of the Royal College of Surgeons the combined schools form the largest medical teaching body in Ireland. These schools are attached by Charter to the Royal College of Surgeons. They are carried on within the College building, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the Professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special histological, pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction.

The diplomata of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

**PRIZES.**—The Barker Prize, £21; the Carmichael Scholarship, £15; the Mayne Scholarship, £15. The Gold and Silver Medals in Surgery, and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £3 and £1, accompanied by medal if sufficient merit be shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on application to the Registrar, Royal College of Surgeons, Dublin.

**THE CATHOLIC UNIVERSITY SCHOOL** is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors.

The following Exhibitions are awarded annually:—Two first year's, value, £12 10s. each; two second year's, value, £10 each; one third year's Royal Exhibition of £12 10s.; one final of £12 10s.; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

#### THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The great want in the colleges of Cork and Galway is a summer session. This necessitates the loss to the student each year of three available working months. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The students do not, however, reside within the college, but halls of residence and licensed boarding houses are provided for those who do not live with friends. The expense of living in the collegiate

towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The winter medical session commences on October 29th and ends about Easter. The scholarships examinations are held in October. An account of the prizes and exhibitions in medicine, the names of the professors, and other information may be found in the advertisements of this issue, and full details may be had on application to—

Belfast, John Purser, LL.D., Registrar.; Cork, Alexander Jaok, M.A.; Galway, Edward Townsend, M.A.

#### DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.  
SESSION 1901-1902.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of chemical manufactures, engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-Associate students may join for any course required. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the associate students at the end of each session. The chemical, physical, zoological and botanical, geological and mineralogical laboratories and drawing schools are open daily for practical instruction. The session commences on Tuesday, October 1st.

The courses of chemistry, physics, botany, geology and mineralogy, and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological and botanical and geological laboratories.

#### THE DUBLIN HOSPITALS.

The clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopedic hospital, a fever hospital, an ophthalmic hospital with two centres, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, i.e., three winter sessions of six months and three summers of three months) within the five years of study. The fee at all general hospitals is £8 in winter, and for the summer £6, or £12 for the entire session of nine months if taken together.

#### GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation of these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds—total, 312 beds. These hospitals are visited each morning at nine o'clock by the Physicians and Surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment for the distribution of trusses to the ruptured poor of Ireland is connected with these hospitals. There are very large ophthalmic, aural,

throat, and gynecological dispensaries, and instruction in these important subjects is given. Eight resident clinical clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, as formerly, but also to those who are qualified in medicine or surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected annually, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoin these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every six months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the secretary of the Medical Board, Dr. Lane Joynt, 84, Harcourt Street, Dublin.
